

**SOCIO-ECONOMIC STUDY OF FARMERS IN
IRINJALAKUDA BLOCK IN THE
COMMAND AREA OF PEECHI
IRRIGATION PROJECT**

By

LATHA BASTINE C.

THESIS

Submitted in partial fulfilment of the
requirement for the degree of

Master of Science in Agriculture

Faculty of Agriculture
Kerala Agricultural University

Department of Agricultural Economics
COLLEGE OF HORTICULTURE
Vellanikkara - Trichur

1982

DECLARATION

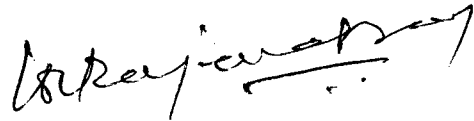

I hereby declare that this thesis entitled "Socio-Economic study of farmers in Irinjalakkuda Block in the Command Area of Peechi Irrigation Project" is a bonafide record of research work done by me during the course of research work and this thesis has not previously formed the basis for the award to me of any degree, diploma, associateship, fellowship or other similar title of any other University or Society.

Vellanikkara,
31.12.'82

LATHA BASTINE. C.

CERTIFICATE

Certified that this thesis entitled "Socio-Economic study of farmers in Irinjalakkuda Block in the Command Area of Peechi Irrigation Project" is a record of research work done independently by Kum. Latha Bastine, C., under my guidance and supervision and that it has not previously formed the basis for the award of any degree, fellowship or associateship to her.

**Mr. D.V. Rajendran,
Chairman,
Advisory Committee,
Assistant Professor,
Department of Agricultural
Economics.**

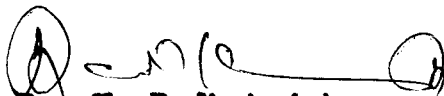

Vellanikkara,

CERTIFICATE

We, the undersigned members of the Advisory Committee of Kum. Latha Bastine, C., a candidate for the degree of Master of Science in Agriculture with major in Agricultural Economics, agree that the thesis entitled "Socio-Economic study of farmers in Irinjalkkuda Block in the Command Area of Peechi Irrigation Project" may be submitted by Kum. Latha Bastine. C. in partial fulfilment of the requirements for the degree.

**Mr. D.V. Rajendran,
Chairman,
Advisory Committee**

**Dr. V. Radhakrishnan,
Member**

**Mr. V.K.G. Unnithan,
Member**

**Mr. K.P. Rameshchandran Nair,
Member**

ACKNOWLEDGEMENTS

I hereby express my sincere sense of gratitude to Mr. D.V. Rajendran, Chairman of the Advisory Committee, for his able and critical guidance and tireless help during the whole course of the present investigation as well as in the preparation of this thesis.

My profound sense of gratitude is expressed to Dr. V. Radhakrishnan, Professor and Head, Department of Agricultural Economics for the critical remarks and valuable suggestions given to me during the course of this investigation.

My indebtedness is also due to Mr.V.K.G. Unnithan, Associate Professor, Department of Agricultural Statistics, for his whole hearted help extended to me in the analysis of the data. I am also grateful to Mr.K.P. Ramachandran Nair, Assistant Professor, Department of Agricultural Extension for his valuable suggestions.

I had the privilege of having the sincere help from all corners, including the officers and staff members of the Agricultural Department and Irinjalakkuda Block Office in the conduct of the survey. I express my heartfelt thanks to them.

The award of fellowship by the Kerala Agricultural University is also acknowledged.

I am also grateful to my parents whose love and constant inspiration made me fulfil this endeavour.

I bow my head before the Almighty, the giver of all good things, without whose help all labour is ineffective and without whose grace all wisdom is folly.

LATHA BASTINE, C.

Introduction

CHAPTER I

INTRODUCTION

Under pressures of increasing population and rise in income, the demand for agricultural products in the country has been increasing. In view of the limited scope for further increasing the area under cultivation, the enhancement of agricultural production to meet the demand has to come through multiple cropping and use of high yielding varieties. For these, water supply in terms of timeliness and adequacy is an important requirement. Without this, it will not be possible to secure rapid increases in yields which the application of modern inputs like high yielding variety seeds, fertilizers, pesticides, etc. is capable of achieving.

The development of irrigation facilities has been one of the major item of state activity in India in recent years and in the Five Year Plans considerable amounts of investments have been made towards this. Since 1950-51, 146 major and 756 medium irrigation projects have been taken up till the end of the Fifth Five Year Plan. It is envisaged to create an additional irrigation potential of 15 m. ha during the Sixth Five Year Plan. This will be made up of 6.5 m. ha from major and medium irrigation schemes with an investment of Rs.6702 crores and 8.5 m. ha from minor irrigation schemes

with a public sector investment of Rs.1415 crores, about 2200 crores of institutional investment and about Rs.1000/- crores of investment from the sources of the farmers themselves.

However, the massive investments that have taken place has not produced results as anticipated. In several cases availability of water for irrigation has been much below the potential. Even the water available is not properly utilized in many cases due to a variety of factors such as organisational, institutional, technical, economic, sociological, etc.*

With a view to find solutions to these problems and to ensure integrated development of command areas of irrigation projects, the Government of India has adopted a policy of setting up Command Area Development Authorities in respect of major irrigation projects. Forty such Authorities were in existence by 1980, covering more than 50 irrigation projects.

As stated above, Command Area Development Authorities are intended to initiate integrated development of the command areas. The activities undertaken by the authority are providing engineering works to enable proper distribution of irrigation water, provide the required agricultural and other

*Jayaraman, T.K. (1980). Some research issues in Irrigated Agriculture under Major Irrigation Projects. Proceedings of the National Seminar on Research Perspectives in Agricultural Economics, T.N.A.U., Coimbatore.

supporting services and to develop a scientific approach to crop production which would enable exploitation of the full production potential of the irrigation projects. The programmes envisaged include developing the irrigation system, arranging a systematic and efficient water management, land levelling, exploitation of ground water, development of cropping pattern suited to the locality, provide for drainage facilities wherever required, consolidate holdings wherever possible, exploit ground water, ensure supply of inputs, marketing, processing and communication facilities and to enable the farmers to take up soil conservation measures, etc.

Command area of Peechi irrigation project

The Dam and Reservoir is located at Peechi, 24 Km east of Trichur town. The dam is built across the Manali river, a tributary of Karuvannur river. The catchment area of the dam was estimated as 107.09 sq.km. It was envisaged to irrigate 17,256 hectares of paddy land in Trichur district by its two main canals and their branches. The dam is constructed with masonry and earth work. Apart from irrigation, the reservoir also supplies drinking water to Trichur Municipality and its adjacent panchayats.

The Left Bank Canal extends to 44.86 Km and would benefit 2848 hectares while the Right Bank Canal measures

36.85 km and expected to irrigate 14,228 hectares which includes 7664 hectares of kule lands. The expenditure on the project till June 1977 was Rs.235 lakhs. Generally water for irrigation is released through the canals during August to December for cultivation of Mundakan paddy. During February water is again released exclusively for the benefit of kule cultivation. The supply of water from the project is exclusively for paddy crop.

For the development of command areas of Peechi, Chalakkudy and Malampuzha projects in Kerala, the Command Area Development Authority - came to be established in Kerala. The Kerala Agricultural University has recently set up a special research cell for command areas. Agricultural development of any nature to be of benefit to the farmer warrants an understanding of the existing socio-economic conditions of the area to be developed. This study is an attempt in that directions and it proposes to understand the present socio-economic status of farmers in the Irinjalakkuda N.E.S. Block area which forms a part of Peechi Command. The specific objectives of the study are:

1. To study the methods and practices followed for cultivation;
2. To study infrastructural facilities available;
3. To understand general, social and economic conditions of farmers in the locality;

4. To study cost and income structure of the farm business;
5. To assess the availability and use of resources;
6. To study savings, investments, assets and debts pattern; and
7. To understand the consumption pattern and standard of living of the farmers.

Review of Literature

CHAPTER II

REVIEW OF LITERATURE

Studies on the socio-economic conditions of farmers in Command areas of irrigation projects or farmers in general are covered in the present review. It also covers the related aspects such as income, expenditure and savings, resource use in agriculture and economics of crop production and dairying.

1. General socio-economic studies in Command areas

The possible ways to derive maximum benefit from the irrigation water of the Chambal valley project were studied by Anand (1960). He came to the conclusion that reclamation of waste lands, mechanisation to help save labour or animals power, provision of adequate fertilizer and other inputs along with intensive extension work could help farmers to achieve this.

Wade (1975) suggested that attention should be focussed on mainly, the alternative approaches to land development and consolidation, effect of rotational irrigation both on aggregate output and income of farmers and the role of water associations in order to enable agricultural development.

Pathak et al. (1977) reviewing on the Kadana Command

7
7

area emphasised the need to strengthen co-operatives in the command area to cater to the farmers' input needs.

Singh (1977) concluded that there is an underutilisation of irrigation facilities in the major and minor irrigation projects studied, to the tune of about 98 per cent. The reasons attributed were, (1) the non-availability of assured and regular supply of water in certain systems, (2) lack of construction of water courses and field canals, (3) non-existence of proper drainage system, (4) lack of proper land levelling and shaping and (5) inadequacy of infrastructure, inputs and wastage of water.

Sisodia (1977) tried to reveal the disadvantages of farmers in the command areas and other areas of Chambal. In the areas not benefitted by the C.A.D. programme he observed, the extent of land holding, quality of land possessed, area irrigated and the intensity of cropping were of low order. The cropping pattern of the farmers in the command area had a better balance between food crops and cash crops, whereas food grains dominated for the farmers in other areas. He has also noted that the net surplus with the farmers in the command areas were better.

In the study conducted by Khuspe and Sawani (1979) in Mula command area project it was found that about 57 per cent of the farmers were underutilising the canal irrigation

facilities. The reasons attributed to this were non-availability of agricultural credit, heavy cost incurred for the repair and maintenance of field canals, undulating terrain and non-availability of agricultural inputs in time.

Suryawanshi and Patil (1980) studied the economics of investment in Girna Command area of Maharashtra. A definite impact was observed on the cropping pattern, crop yields and the income levels of farmers. The benefit-cost ratio increased from 1.14 to 1.2. He has also observed that the extension agency reached the farms, the ultimate areas to develop. A qualitative change on the attitude to adoption has also been recorded.

Bagi (1981) analysing the economics of irrigation in crop production at Haryana concluded that the technical efficiency was higher on irrigated farms. The relative allocative efficiency of the inputs were also found to improve.

2. Income, expenditure and savings

Parthasarathy (1972) studied the income and expenditure pattern of agricultural families according to type and size of farms in Andhra Pradesh. In all types and size of farms, family expenditure constituted a major item of expenditure followed by crop and livestock enterprises.

99

The study conducted by Deole et al. (1972) in the command area of Purna project in Parbhani district of Maharashtra revealed that with regard to the non-beneficiaries crop production accounted for about 68 per cent of the gross annual income per holding while in the case of beneficiaries it was 76 per cent. The respective percentages of crop expenditure were 46.25 per cent and 51.81 per cent. The holdings below 10 acres did not have any savings.

Chawla et al. (1975) studied the income and expenditure pattern of small farmers in Amritsar district. The study revealed that the income from farm production varied positively with farm size. Food items accounted for maximum expenditure followed by clothing, lighting, housing, miscellaneous items, medicine, social ceremonies, food and education. The expenditure on food items varied inversely with farm size. Expenses on light, medicine, clothing, fuel and education varied positively with farm size.

Patil et al. (1978) observed that food was the most important item of expenditure in the Girna project area, accounting for more than 50 per cent of the total family expenditure. The next in importance were clothing and bedding, fuel and lighting, education, recreation, travelling, medical etc. Of the total family income 73.76 per cent was from crop

production followed by livestock production (12.39 per cent). The income from wages earned, business and service, hiring of implements and animals, etc. also contributed 4 to 5 per cent each to the total income.

Patel et al. (1980) in their socio-economic study of Ghod Command area (Maharashtra) showed that food was the most important item of expenditure accounting for 53 per cent of the total family expenditure. Of the total farm income 73.34 per cent came from crop production. The other sources were livestock (11.98%), wages and services (5.92%), hiring of implements (2.06%), poultry (1.16%), etc. It was observed that the income of small farmers largely depended on the employment activities other than crop production.

Sidhu et al. (1980) studied the income and expenditure pattern of Punjab farmers. The study revealed that the major share of income of the farmers is contributed by crops followed by dairying and other sources. Farm business income per hectare showed an inverse relationship with the size of the farm. But per capita farm business income was found to have positive relationship with the size of the farm. An inverse relationship was noticed between farm expenditure per hectare and the farm size. Per capita farm family domestic expenditure was found to have a positive relationship with the farm size. Surplus from agriculture showed a positive relationship with the farm size.

3. Resource use in agriculture

The study conducted by Negi et al. (1972) in the small farms of Hainital Tarai revealed that land was the most important resource which has significant and positive impact on almost all crops. Fertilizers showed a significant and positive impact on high yielding varieties of wheat.

Desai (1973) studied the economics of resource use on sample farms of central Gujarat. The study concluded that the uncertainty prevailed with respect to irrigation resource caused an uneconomic use of labour and sub-optimum use of fertilizers and manures in less developed regions. In regions where irrigation facilities are reliable and adequate the farmers maximised the net returns over all inputs.

The study conducted by Singh et al. (1975) in Meerut district of Uttar Pradesh showed that the percentage of area under food crops decreased as the size of holding increased. Input, output and net income per farm showed an increasing trend with an increase in the size of holdings, mainly because of the higher cropping intensity and higher expenditure on cash inputs.

Singh et al. (1975) studied the income, investment and cropping pattern of small farmers in Kalyanpur Block, Uttar Pradesh. The study showed that 80% of the total input was accounted for by three factors namely human labour (20%),

bullock labour (21%) and rental value of land 38%. Manures and fertilizers accounted for about 8 per cent of the total cost.

Chawla (1975) studied the small farmers expenditure on modern inputs in district Amritsar, revealed that the small farmers did not apply the recommended dose of fertilizers and irrigation due to low income, high prices and ignorance while other farmers reported difficulties with regard to power supply.

Rathore et al. (1975) analysed the economy of small farms in Udaipur district of Rajasthan. He concluded that irrigated farms could generate substantial income and production. Labour use was also greater in irrigated farms, so also underemployment. He stressed the need for taking up subsidiary occupations.

A study conducted by Acharya and Sukla (1975) analysed small scale farming in southern Rajasthan. Estimates of six Cobb-Douglas type of production function and corresponding marginal value products revealed that total labour, family labour, hired labour, non-conventional capital, non-mechanical capital and variable expenses exerted a significant effect on output. The effect of land, fixed capital, conventional capital input and machine input did not turn out to be significant. Different forms of capital input for which the

production elasticities were significant had value of HYVs seeds, fertilizers and insecticides as common items. It also concluded that the adoption of labour intensive HYV crops increased the intensity of cropping and use of fertilizers and insecticides were instruments for increasing the incomes of small farmers.

Dhawan and Bansal (1977) studied the rationality of the use of various factors of production on different sizes of farms in Punjab. The study brought out that land resource was efficiently used on the small and medium farms. The small farmers should curtail the use of human labour, expenditure on irrigation and drought animals on the one hand and increase the expenditure on seeds and manures and fertilizers and milch animals. The study also revealed that all categories of farms could increase their income by more investments on milch animals and through intensive use of chemical fertilizers.

Desai (1977) studied cropping pattern of farm families of Surat district. The results showed that increasing the availability of net irrigable land would shift the crop pattern in favour of more remunerative and also labour intensive crops such as sugarcane, banana and high yielding variety paddy. The shift would in turn increase the net income of an average farmer.

The study conducted by Palaniswamy and Rajagopalan (1977) showed that the family labour input was more in small farms where it was the permanent labour in large farms. The total labour input per unit area decreased as the size of the farm increased.

Patil et al. (1978) conducted a socio-economic survey of Girna irrigation project area in Jalgaon district in Maharashtra. The study revealed that for almost all crops, the use of fertilizers was below the recommended doses. The utilization of nitrogen was relatively more as compared to phosphorus and potash.

Patil et al. (1980) in their investigation into the socio-economic conditions of Ghed irrigation project area concluded that after the introduction of irrigation over a period of time, the production levels had been increased considerably. They made note of the increased use of hired labour, low use of fertilizers, etc. in the study area.

4. Economics of crop production and dairying

Singh (1966) studied the cost of cultivation in relation to size of holding. The results showed that there is an increasing trend in output per acre and a decreasing trend in human and bullock labour inputs and so the cost of cultivation. The minimum cost of cultivation was recorded for a holding size of about 40 acres.

Chaurasia and Singh (1972) studied the economics of local and high yielding varieties of wheat in Panagar village of Madhya Pradesh. The results showed that high yielding varieties area comparatively more labour intensive and responsive to fertilizer than the local varieties. They require more expenditure per acre of which about 57 per cent forms the material cost.

Patil et al. (1978) studied the cost of cultivation of various crops in Girna project area in Maharashtra and found out that the cost of cultivation per hectare of paddy was Rs.1865.47 with the total output of 11.67 quintals. The net profit per hectare was Rs.610.59. The per hectare cost of cultivation of banana was Rs.7492.97.

Patil et al. (1980) studied the cost of cultivation of crops in the Ghod command area of Maharashtra and found that, that for paddy worked out to Rs.1740.45 with the output of 11.72 quintals. The profit per hectare was Rs.885.07.

The study conducted by Sidhu et al. (1980) on the farm expenditure pattern of Punjab farmers revealed that the farm expenditure per hectare decreased with the increase in the size of holding. The contribution of different agricultural inputs in the total farm expenditure in forms of percentages was 31.34, 26.84, 10.56, 8.13, 6.84, 5.62, 4.85, 3.59 and 2.43 on labour, fertilizer, seed, feed and fodder, land

revenue/land rent/crop cess, irrigation charges, fuel and mobile oil, insecticides and weedicides and miscellaneous items respectively.

Bal et al. (1980) studied the economics of milch animals and they concluded that the contribution of dairy business to total farm business income was low and the input-output ratio in case of milch animals was smaller. However the performance of milch animals was better on medium and small farms. The contribution of the dairy enterprises to total farm business income in small, medium, large and overall size of farms were 15.58%, 14.03%, 6.38% and 13.16% respectively. Input-output ratios were Rs.1.48, Rs.1.53, Rs.1.29 and Rs.1.43 from milch animals in the various size groups and Rs.1.69, Rs.1.76, Rs.1.64 and Rs.1.70 from crop production.

Balishter and Singh (1980) studied the economics of crop and livestock enterprises in Bichpuri block of Agra district of western U.P. Their study revealed that the output per animal was the highest in small farms and lowest on large farms. The share of crops and livestock in total farm output were 72.16 per cent and 27.84 per cent, respectively. In the case of livestock the input-output ratio was higher in small farms as compared to crop enterprise, indicating a better scope for livestock enterprise as a subsidiary occupation of the farms.

Singh et al. (1980) studied the economics of livestock production in relation to its contribution to the gross farm income and employment in District Farukhabad (U.P.). It showed that of the average gross farm income and expenses of Rs.4991.22 and Rs.3553.88, the livestock production accounted for 28.57 per cent in the former and 29.48 per cent in the later. The percentage contribution made to total farm income, expenses and employment by livestock was higher on small farms as compared to large sized farms.

The study conducted by Verma and Tewari (1980) in district Unnao, Uttar Pradesh revealed that she-buffaloes gave higher return than cows. The contribution made by livestock to gross income and expenses were 21.65 per cent and 24.19 per cent respectively as against 78.35 and 75.81 per cent by crop production. The contribution of livestock production to the gross farm income was higher on the smallest size group than the largest one.

Radhakrishnan et al. (1981) reported that the cost of cultivation of paddy during 1978-79 in Trichur district was Rs.2240.34 per hectare excluding rent for high yielding varieties of paddy while it was Rs.1905.00 per hectare for local varieties. The cost per quintal was estimated as Rs.80 for HYV₂ and Rs.107 for local varieties. The benefit cost ratio was 1.32 for HYV₂ and 1.12 for local varieties at total cost excluding rent.

Radhakrishnan et al. (1981) studied the cost of cultivation of paddy in Kerala during 1979-80. The results showed that at cost C, excluding rent, cost per quintal of high yielding varieties was Rs.52.88 and traditional varieties Rs.93.60 in Trichur district. The benefit-cost ratio worked out to 1.64 for high yielding varieties and 1.14 for traditional varieties.

Materials and Methods

CHAPTER III

MATERIALS AND METHODS

Coverage

The study covers the farmers in Irinjalakkuda Block in the Command area of Peechi Irrigation Project. The Peechi Dam was built across the Manali river and was meant to provide irrigation to the paddy crop in the command area. It supplements the water needs of the Mundakan paddy in the command area besides providing irrigation to the Punched crop in the kole lands.

Sample design

Two stage simple random sampling was adopted for the study. At the first stage, five Panchayat wards were selected randomly, from among the panchayat wards in Irinjalakkuda Block. In the second stage, twenty farm families were selected randomly from each panchayat ward. The total size of the sample was thus limited to one hundred as it was felt that an individual would not be able to cope with a larger sample, however desirable that may be from other points of view. The panchayats and wards selected for the study were the following.

<u>Name of Panchayat</u>	<u>Name of ward</u>
1. Karalam	Karalam
2. Karalam	Chemmanda
3. Porathissery	Karuvannoor
4. Kattoor	Karanchira
5. Muriad	Pulleer

The total 100 holdings were further classified according to the size of operational holding and also according to the gross income of the family. The different size groups, their designation used in the study, different income groups and their designation are given in the following tables.

Table 3.1. Classes of sample holding and their designations

A. According to size of holding

Sl.No.	Holding size	Designation
1	Less than 0.4 hectares	S ₁
2	0.4 to 0.8 hectares	S ₂
3	0.8 to 1.2 hectares	S ₃
4	1.2 to 1.6 hectares	S ₄
5	1.6 hectares and above	S ₅

B. According to income

Sl.No.	Income	Designation
1	Less than Rs.8,000/-	I ₁
2	Rs.8,000 to Rs.15,000/-	I ₂
3	Rs.15,000 to Rs.25,000/-	I ₃
4	Rs.25,000 to Rs.35,000/-	I ₄
5	Rs.35,000 and above	I ₅

Collection of data

The data were collected using well structured schedules designed for the purpose. A copy of the schedule used is given in the Appendix. The schedules were designed to gather information on the various aspects such as assets on the farms, utilization of inputs for the crops, their outputs, expenditure on maintenance of family, etc. Personal interview method was adopted for the collection of information. The information were gathered for the period from 1st June 1981 to 31st May 1982.

Concepts used in the study

1) Human labour:

a) Family labour - The actual work done by the members of the family on crop and livestock production was considered

as family labour. It was evaluated at the wage rates prevailing in the concerned ward for the purpose of calculation of the cost.

b) Hired labour - The actual paid wage labour engaged was considered as hired labour. It was evaluated at the rates paid by the farmers, including payments in kind wherever applicable. Hired labour consisted entirely of casual labour.

ii) Bullock labour

Bullocks for the various operations were generally hired in by the farmers and the rates paid were considered. In the few cases where bullocks were owned, their costs were evaluated at the rates paid for hired bullock labour.

iii) Tractor hours

Tractors were used by some of the respondents for ploughing by hiring in at hourly rates. For the purpose of costing these were evaluated at the actual rates paid.

iv) Seeds, manures, fertilizers and pesticides

For seeds and manures purchased, actual amounts paid has been accounted. Farm produced seeds and manures have been evaluated on the basis of prevailing rates.

v) Irrigation charges and land revenue

Irrigation charges included the water charges actually

paid to the Revenue Department for the use of canal water and also to the irrigation committees or kule committees. In the case of well irrigation actual charges paid for fuel used are considered. Land revenue was considered as the actual amounts paid to the Revenue Department by the farmers.

vi) Rental value of owned land

Hiring in and leasing out land was not reported among the sample farmers. Hence actual quantum of rent could not be found out. The rental value of owned land has been considered at one-fifth of the value of gross produce from the various crops.

vii) Interest on working capital

Interest on working capital was calculated at 12.5 per cent per annum for four months in the case of each crop of paddy and for whole year for annual and perennial crops.

viii) Interest on fixed capital

Interest on fixed capital was computed at the rate of 10.25 per cent on the value of implements, machinery, sprayers, etc. The interest charges were allocated for individual crops in proportion to the area under each crop.

ix) Depreciation

Loss of value in use is depreciation. For pucca

buildings it was charged at the rate of two per cent and for Kacha buildings at the rate of five per cent. For implements the rates of depreciation charged were 15 per cent for iron implements and 20 per cent in the case of wooden implements, baskets, ropes, etc. The depreciation for pumpsets was taken as five per cent and that for sprayers ten per cent.

x) Cost concepts

The analysis was made using different cost concepts - cost A₁, B and C. Since leasing in of land is not practised in the study area, cost A₂ was not considered.

a) Cost A

The various items included under this head were:

1. hired human labour
2. hired bullock labour
3. owned bullock labour
4. seeds (farm produced and purchased)
5. manures and fertilizers
6. expenditure on irrigation
7. expenditure on crop protection
8. depreciation of implements, machinery, sprayers, etc.
9. interest on working capital

b) Cost B

Cost B consists of cost A, rental value of owned land and interest on fixed capital.

c) Cost C

Cost C consists of cost B and imputed value of family labour.

xi) Measures of income

Farm business analyses have been carried out by applying the different measures of income. They are:-

a) Gross income

Income obtained by the sale of main product and by-product comprises gross income and were worked out at the rates which prevailed in the concerned areas at the harvest periods. Income on different cost concepts were worked out as follows:

b) Farm business income

The difference between the gross income and cost A represents farm business income of the cultivators.

c) Family labour income

The difference between gross income and cost B (i.e., profit at cost B) represents the income of the cultivators on account of his own and family labour.

d) Net income

The difference between the gross income and cost C (i.e., profit at cost C) represents the net return for the farm enterprise.

e) Farm investment income

It was computed by deducting the imputed value of family labour from the farm business income.

f) Input-output ratio

Input-output ratios were worked out for the different enterprises and farm business as a whole by dividing the gross income by the total cost.

xii) Adult consumption units

For calculating the consumption to study the nature of family consumption, the family members of the different category were equated on the basis of the following equivalence, which was standardised by Khare (1975).

<u>Male/Female</u>	<u>Age in years</u>	<u>Consumption unit</u>
Male or female	0-6	0.45
Male or female	6-14	0.75
Female	14 and above	0.90
Male	14 and above	1.00

xiii) House-hold expenditure

a) Food

This includes cost of rice, pulses, oils, sugars, vegetables and other articles which form a part of the daily diet of the farm family.

b) Fuel and lighting

This consists mainly of expenditure on firewood, kerosene and electricity charges.

Other items include expenditure on education, medicine, travel, recreation, beverages, house taxes, etc.

Area of study

CHAPTER IV
AREA OF STUDY

Irinjalakkuda Block is situated 15 km south of Trichur bounded on the north side by the Cherpu and Anthikad blocks, on the south by Velliangallur block, on the west by Kodakara and Mala blocks, and on the eastern side by Thalikulam and Mathilakam blocks.

The average annual rainfall is 2633 mm with a maximum temperature of 39°C.

The Block comprises of five panchayats namely, Muriad, Parappukkara, Porathissery, Karalam and Kattur, on the southern part of Trichur district, extending over 96.92 sq.km. The total population according to 1971 census was 86,282 and was estimated at 1,03,263 in 1978. The Table below gives the panchayatwise area and population.

Table 4.1. Estimated population for Irinjalakkuda Block for the year 1978

Sl. No.	Panchayat	No. of Wards	Area	Population	No. of households
1	Muriad	9	21.83	20,098	3,835
2	Parappukkara	10	21.36	27,588	5,466
3	Porathissery	10	21.46	26,791	4,734
4	Karalam	9	20.58	16,818	3,850
5	Kattoor	8	11.69	11,968	2,400
			96.92	1,03,263	20,285

Source: Block Office, Irinjalakkuda N.E.S. Block.

Infrastructural facilities

Agricultural modernisation to a great extent depends upon the facilities available in the region. They include service infrastructure consisting of credit facilities, marketing services, input supply services, research and extension services and physical infrastructure consisting of transport, irrigation, power and storage facilities. The block is well connected by roads which extend to about 73 km of semi pucca roads and 207 km of kaccha roads. The Trichur-Kodungalloor road traverses through the block and is connected to a network of kaccha roads. The Kodungalloor-Guruvayoor road passes through Kattoor - one of the panchayats. On the eastern side of the block passes the National Highway-47. The Irinjalakkuda railway station is about five kilometers from the block.

A part of Karuvannoor river passes through the northern and western boundaries of the block. There is a fresh water lake in the block - Muriad kayal. Two irrigation projects supply water to the block - the Peechi Irrigation Project and the Chalakkudy Irrigation Project.

Telephone facilities are also available in all localities - with telegraph offices at Karuvannoor, Madaikenam and Nellayi. A number of small markets dealing with a host of commodities are spread throughout the block.

The services of primary co-operative societies are available in all the panchayats. Branches of commercial banks function in the Irinjalakkuda municipal area which is about five kilometers away from the block headquarters. In the block area there are offices of Indian Overseas Bank at Karuvanneer, Cochin Bank at Karalam and Kattoor panchayats. A number of professional money lenders also operate in this area.

There is one government hospital in the Kattoor panchayat and another in the municipal area. A primary health centre functions in the Muriad Panchayat and a number of family welfare sub-centres distributed in the block area.

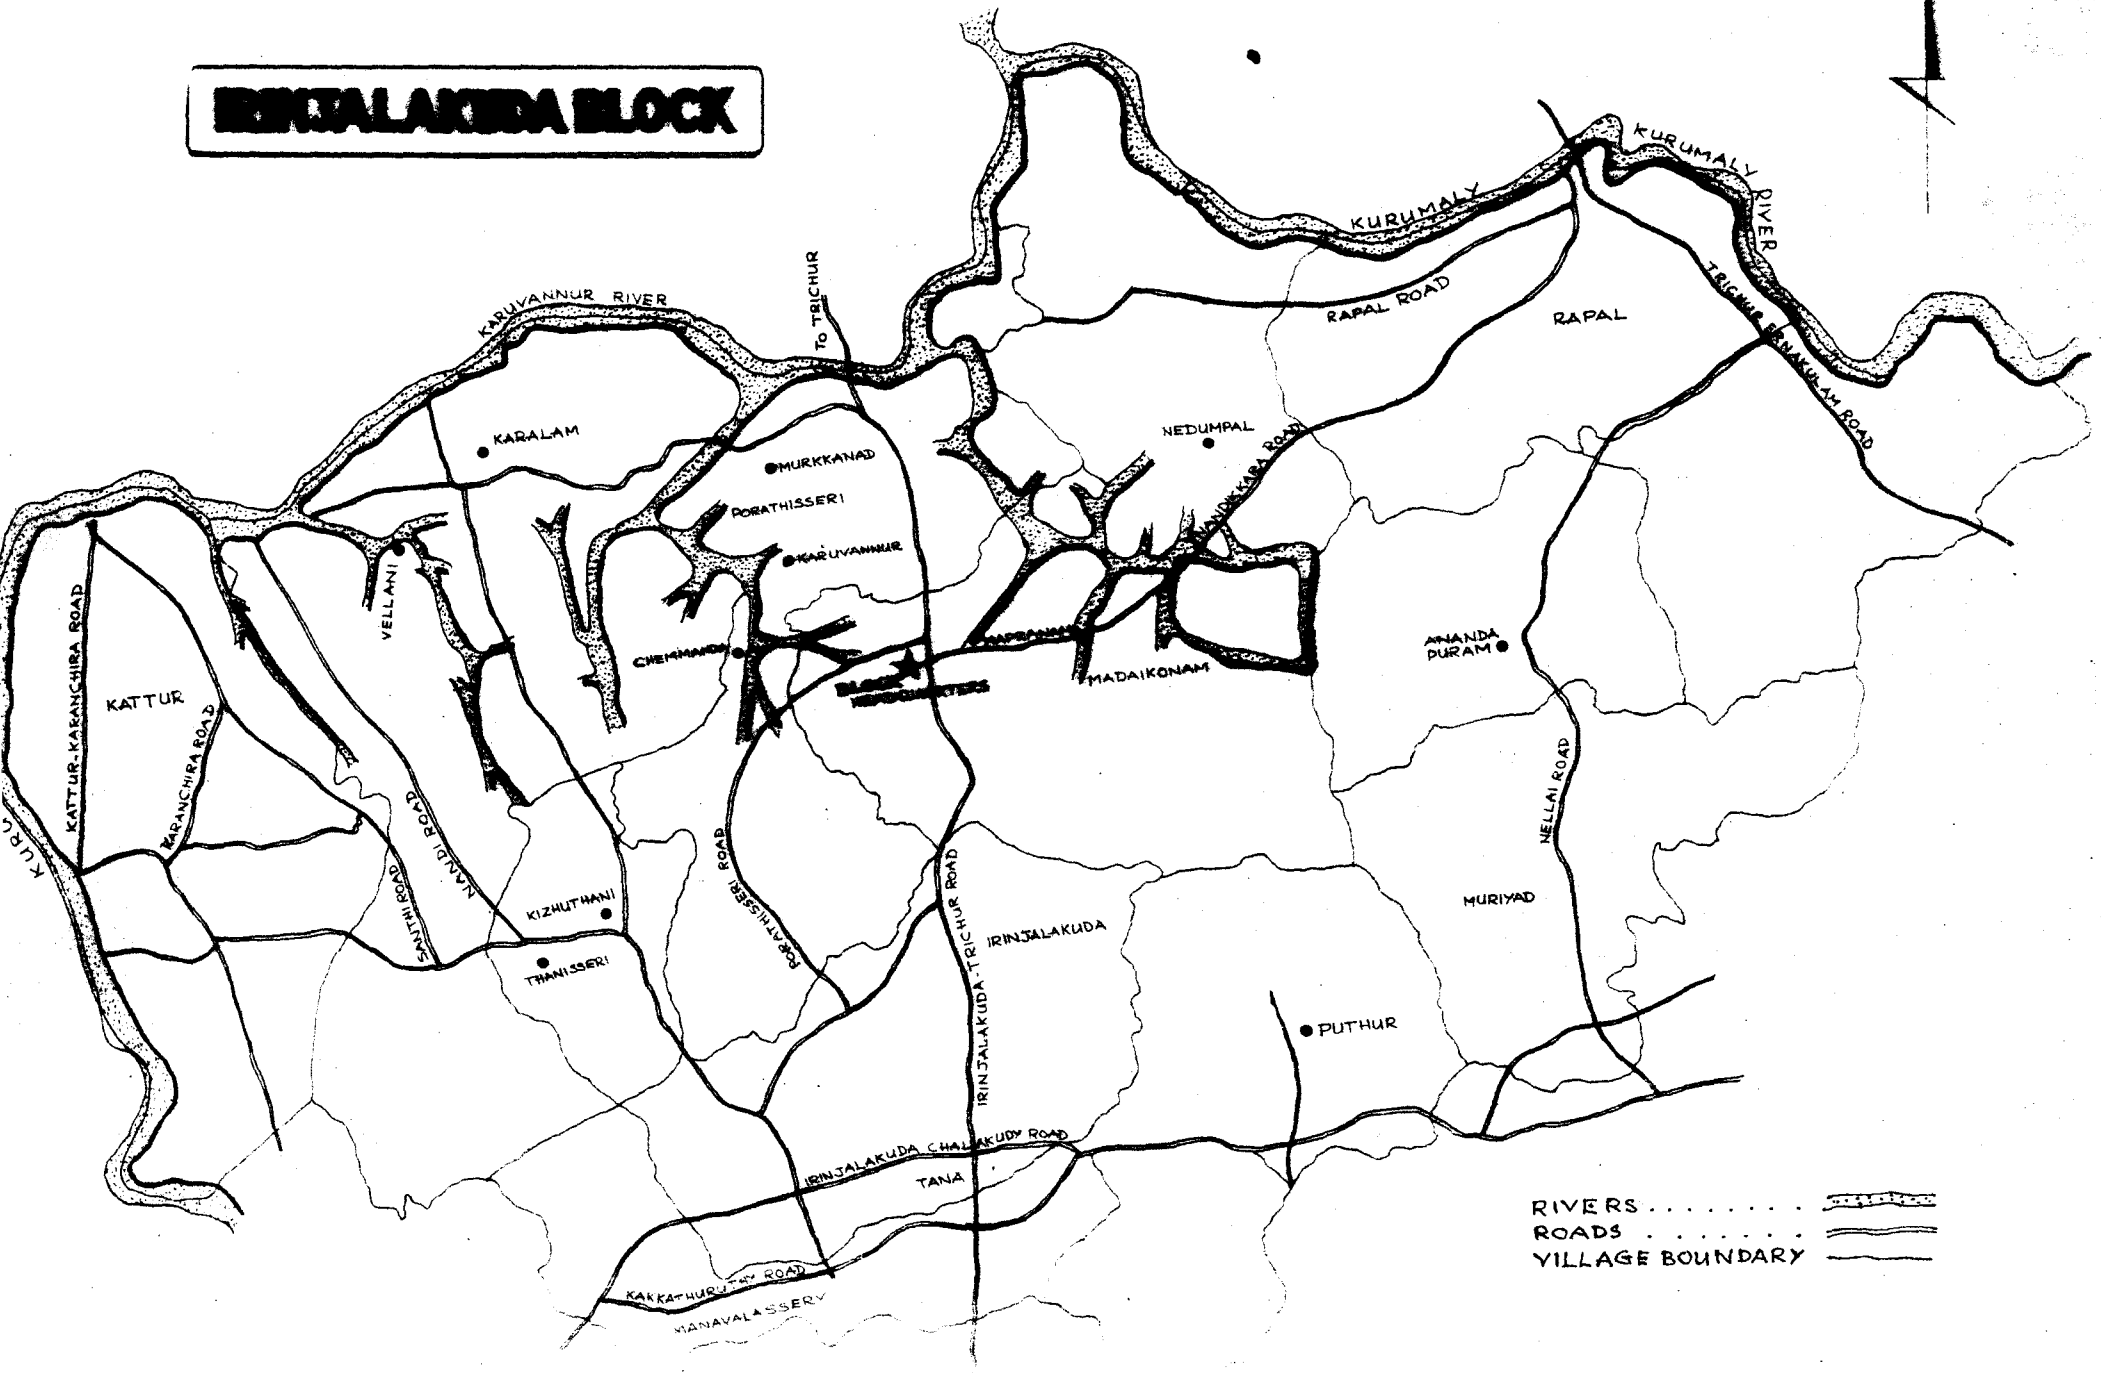

Within the block area there are five high schools, eleven upper primary schools and 16 lower primary schools. Educational facilities are available in the municipal area also.

Tile manufacturing is the only established industry in this block area. Making bricks during seasons utilizing clay from paddy fields is also common.

Two major soil types are seen in the northern part namely, the alluvial soil referred as kole lands which are heavy in texture and the laterite soil which is the predominant soil in garden lands. The soil is rich in organic matter, nitrogen and potash, deficient in phosphorus. The alluvial soils are periodically subjected to salt water inundation.

It is estimated that about 3500 hectares of wet lands are brought under cultivation of paddy. Of this about 1540 hectares are in the kele region. Paddy is being raised as a single crop in 780 hectares, double crop in 1200 hectares and triple crop in 190 hectares. In the garden land coconut occupies 2610 hectares, tapioca 850 hectares, arecanut 508 hectares, banana and plantains 455 hectares, cashew in 416 hectares and a variety of other crops are also cultivated.

General characteristics of the sample farms

CHAPTER V

GENERAL CHARACTERISTICS OF THE SAMPLE FARMS

Knowledge on the socio-economic conditions like the population, its structure, educational status, occupation, income, etc. are of great value in the context of development. In the following pages an attempt is made to examine the general socio-economic conditions of the sample farm households.

The sample was classified into five categories on the basis of size of holding. They were also grouped into five on the basis of gross income of families. The distribution of the farmers according to their size of holding is given in Table 5.1.

The average size of the holding was 1.23 hectares. Twentyseven per cent of the sample farms was in the size group between 0.40 hectare to 0.8 hectare (1 to 2 acres). This group accounted for only 13.76 per cent of the total area for the sample. Twentyfour per cent of the total farmers had holdings of more than 1.6 hectares (4 acres) and they possessed 50.41 per cent of the total area, with an average size of 2.58 hectares.

The distribution of sample according to income groups shows that the number of holdings in the different income

Table 5.1. Distribution of sample farm households according to different holding size

Sl. No.	Holding size (in hectares)	Number of holdings	Per cent to total number	Total area owned (in ha)	Percentage to total area	Average size of holding (in ha)
1	0.4	14	14.00	4.00	3.26	0.29
2	0.41-0.8	27	27.00	16.89	13.76	0.63
3	0.81-1.2	22	22.00	21.81	17.77	0.99
4	1.21-1.6	13	13.00	18.17	14.80	1.40
5	1.6 and above	24	24.00	61.88	50.41	2.58
Total		100	100.00	122.75	100.00	1.23

Table 5.2. Distribution of sample farm households according to income

Sl. No.	Income groups (in rupees)	Number of holdings	Percentage to total number	Total area owned (in ha)	Percentage to total area	Average size of holding (in ha)
1	Upto 8000	23	23.00	15.16	12.35	0.66
2	8000-15000	23	23.00	18.26	14.88	0.79
3	15000-25000	23	23.00	32.66	26.61	1.42
4	25000-35000	9	9.00	12.09	9.85	1.34
5	35000 and above	22	22.00	44.58	36.31	2.03
Total		100	100.00	122.75	100.00	1.23

classes were more or less the same except in the income group of Rs.25,000 to 35,000 where it accounted for only nine per cent. More than 36 per cent of the total area owned was by farmers in the income group above Rs.35,000/- and they had an average area of 2.03 hectares. The area owned by those in the income group of Rs.25,000 to Rs.35,000/- accounted for only 9.85 per cent. The distribution of the sample farmers into the different classes are shown in Tables 5.1 and 5.2, sizewise and incomewise respectively.

The composition of the members of the sample families classified according to the different holding size groups is given in Table 5.3. The total number of members in the respondent families was 656 of which 51.98 per cent was males and 48.02 per cent are females. The average family size was 6.56.

The largest family size of 7.27 was found in S_3 while the lowest family size in S_1 , with an average family size of 6.00. The distribution between males and females was almost equal with more males in S_4 while females were more in group S_5 .

Among the different size groups it could be seen that the proportion of family members below 6 years were more in the first group accounting for 10.34 per cent followed by the group S_5 (7.62 per cent), S_3 (6.88 per cent), S_4

(4.55 per cent) and S₂ (3.72 per cent). The proportion of the members of the age group 60 and above was the highest in S₄ (10.23 per cent) followed by S₅, S₃, S₂ and S₁.

If one consider, the age group of between 15 to 60 to contribute to production, the sample on an average had 68.44 per cent members in the age group 15 to 60, which is regarded as the working age group. 31.56 per cent or nearly one-third of the total members of the households were outside the working age group. This worked out to be 2.07 members per family. The work force consists of almost 53 per cent males and 47 per cent females. The percentage of people in the age group of 15 to 60 was lowest in the first size group (64.04) and highest in the second size group. Among the different holding size groups the proportion of people in the age group of 15 to 60 did not show much variation.

Table 5.4 shows that the proportion of people in the age group 15 to 60 ranged from 61.53 in the fourth income group to 70.47 in the second. This indicates that a sizeable part of income of farmers are to be utilized for purposes not directly related to improvement in production.

Educational status

Kerala is recognised to be in the forefront considering the extent of literacy. The sample averages also indicated the same. Of the total number of 656 members in the sample

41

families 5.64 per cent - coming in the age group below five years are yet to receive education. Among the balance 619 members it is seen that 85.21 per cent are literate. Literacy was higher among the males accounting to 87.68 per cent while that for females was 82.54 per cent.

On a further analysis of literacy it was seen that all the literates in the sample have attended schools, but to varying levels. While 15.24 per cent had education upto the primary school level, 18.90 per cent attended middle school, 36.43 per cent attended high school, 6.7 per cent attended College. Graduates accounted for 6.25 per cent of the total and post-graduates 1.52 per cent.

Occupational structure

It was generally observed that a sizeable proportion of sample families, to the tune of 67 per cent, were getting income from other occupations along with agriculture. The nature of employment were wage labour, petty trade, professions, government service, etc. Twelve per cent of the sample families were getting income from wage labour and petty trades. Another 12 per cent received income from specialised jobs. Twentyeight per cent of the sample families had accepted services as their major source of income. Fifteen per cent of the total families are engaged in more than two occupations. The details are presented in Table 5.7.

(Figures in parentheses are percentages)

Table 5.10. Occupational distribution of the income earners of households
(income groupwise)

(in numbers)

Sl. No.	Income group	Main occupation					Total number	
		Agriculture	Labour	Trade	Profession	Service		Others
1	I ₁	14 (56.00)	4 (16.00)	-	2 (8.00)	2 (8.00)	3 (12.00)	25 (100.00)
2	I ₂	12 (38.71)	2 (6.45)	3 (9.68)	5 (16.13)	7 (22.58)	2 (6.45)	31 (100.00)
3	I ₃	15 (44.12)	3 (8.82)	2 (5.88)	3 (8.82)	8 (23.54)	3 (8.82)	34 (100.00)
4	I ₄	3 (18.75)	-	1 (6.25)	-	10 (62.50)	2 (12.50)	16 (100.00)
5	I ₅	10 (23.26)	2 (4.65)	2 (4.65)	1 (2.33)	27 (62.78)	1 (2.33)	43 (100.00)
Total		54 (36.24)	11 (7.38)	8 (5.38)	11 (7.38)	54 (36.24)	11 (7.38)	149 (100.00)

(Figures in parentheses are percentages)

The occupational distribution of respondents classed into the different income brackets showed that the dependence on agriculture in I₁ was higher, while in I₄ none of the respondents solely depended on agriculture. The distribution is presented in Table 5.8.

The occupational distribution of the income earners among the sample households is presented in Tables 5.9 and 5.10. In total 149 members from the different families earned income. According to the number of wage earners, agriculture and service were found to be the major sources of income.

The proportion of people engaged in agriculture to the total income earners was found to be the highest in S₄ (50 per cent) followed by S₂, S₅, S₁ and S₃. The proportion of people engaged in services was the highest in S₅ followed by S₂ and S₃. In S₁ the major occupation of one-third of the total wage earners was agriculture.

Among the different income groups the proportion of people engaged in agriculture was the highest in I₁ (56 per cent) followed by I₃ (44.12 per cent). In groups I₅ and I₄ majority of the people were engaged in services (62.79 and 62.50 per cent respectively).

Land use pattern

The land use pattern of the different size groups is

Table 5.11. Land use pattern of the sample (size groupwise)

Cropping intensity	89		98		119		126		113		111	

represented in Table 5.11 for the selected households. The total area owned by the sample farmers was 122.75 hectares. In all, 1.32 hectares were put to non-agricultural uses. The net cropped area worked out to 121.43 hectares. The availability of net cropped area per farm was 1.21 hectares, while the total holding per farm was 1.23. The cropping intensity was 111 per cent on an average. The total holding of farmers consisted of wet lands and garden lands almost in equal proportions on an average.

The average net area cultivated was found to increase with the size of holdings. It was 0.28 for S_1 , 0.61 for S_2 , 0.98 for S_3 , 1.38 for S_4 and 2.56 for S_5 . The same trend was noticed in the case of average area irrigated. The proportion of area irrigated to the net area was found to be the highest in S_5 (84.33 per cent) followed by S_2 (83.08) and S_4 (81.82). The average worked out to 81.92 per cent.

The percentage of area irrigated to net area was highest in I_5 (83.42 per cent) followed by I_2 (83.41 per cent) and I_3 (82.53 per cent).

Cropping pattern

Table 5.13 shows the cropping pattern of the sample holdings. The total cropped area was found to be 134.53 hectares. Of this 55.8 hectares were garden lands and 78.73 wet land which worked out to 41.49 per cent and

58.51 per cent respectively. Of the total gross cropped area 58.51 per cent was under paddy, 32.97 per cent under coconut and 3.64 per cent under arecanut. The area under banana, pepper, cashew and other crops consisted of 0.85, 0.27, 1.6 per cent respectively. The proportion of wet land to total cropped area was found to be the lowest in S_1 (45.65 per cent) and the highest in S_4 (67.53 per cent). The high yielding variety coverage was highest for puncha paddy, in S_1 (80.15 per cent) and the lowest in S_4 (35.43 per cent). But for the mundakan season, the HYV coverage was highest in S_3 (56.52 per cent) and lowest in S_4 (10.67 per cent). In size group S_1 40.1 per cent of the total area (1.66 hec) was under coconut, which is the highest proportion of area under a single crop to the total area.

The area under each crop per farm is also worked out and is presented in Table 5.13. Wet land per farm was found to be increasing with size of the holdings. It was 0.14 hectare in first holding size class and 1.77 hectares in the highest holding size class, the average being 0.79 hectare. The average area under coconut was found to be 0.44 hectare and the per farm area under coconut was found to be increasing with an increase in total size of the holdings. The per farm area under arecanut and banana, on average were found to be 0.05 and 0.01 hectare respectively. The respective per farm

area for cashew and other crops worked out to 0.02 and 0.03 hectare. Per farm total garden land was found to be 0.56 hectare. Average per farm cropped area was found to be 1.35 hectares. Per farm gross cropped area was found to be the highest in S₅ (2.90 hectares) and the lowest in S₁ (0.30 hectare).

The income groupwise cropping pattern is presented in Table 5.14. The percentage of area under paddy was found to be the highest in I₄ (65.54) followed by I₃ (60.67) and I₅ (57.33). The proportion of area under coconut which is the most important cash crop in the area was the highest in I₂ (37.36 per cent) followed by I₅ (34.84 per cent) and I₃ (31.17 per cent). The per farm area under coconut was found to be the highest in I₅ (0.80 hectare) and the lowest in I₁ (0.17 hectare).

Capital assets

The investment by the farmers has been broadly classed into land, livestock, buildings, implements, machinery and shares. Since the average size of farms varies from 0.29 hectare to 2.58 hectares for the different holding size groups, it would be of interest to understand the asset position both per farmer as well as per hectare. Such a distribution of the assets for the holding size groups are presented in Table 5.15. On the whole it was seen that the investment on land accounted

for the bulk of the total assets (94.13 per cent). The total asset value of land per farmer in the sample was Rs.388451.80. The per hectare value of land was Rs.316457.67. In all the size groups, the proportion of land in the total assets was very high. It was more than 90 per cent for group S₃, S₄ and group S₅ recording the highest (97.24 per cent). It was 87.13 per cent in S₂ and 77.74 per cent in S₁. The value of land per farm was found to be over 10 lakhs in group S₅, over 2.5 lakhs in group S₃ and S₄, around 1.5 lakhs for group S₂ and little more than Rs.68,000 for group S₁.

The average value of livestock was about Rs.2000 which was below 1 per cent of the value of total assets. Residential buildings on an average accounted for 4.59 per cent of the total assets. The proportion of the value of buildings for the different size groups to the total assets were found to decrease with the increase in holding size group. The highest proportion was in group S₁ (18.25 per cent) and the lowest in group S₅ (2.11 per cent). Similar trend is also noticed for the farm house and the cattle shed. The average investment on implements was 0.46 per cent. The ownership of shares in co-operatives accounted for a meagre proportion of total assets with an overall average of 0.01 per cent.

The total assets per farm for the sample was worth Rs.412672.25. It was found to be increasing with increase

in size of holding. Total assets per hectare on an average was Rs.356189.21. It was the highest for the group S₅.

The trend in capital investment among different income groups both per farm and per hectare remained more or less similar to that of holding size groups. The total value of assets found to be increasing with an increase in income.

The distribution of total assets according to different income groups are presented in Table 5.16. It may be noted that both in the case of holding size groups as well as of income groups, the average assets per farmer increased with the increase in their holding or income.

Livestock

Different types of domestic animals and birds were found to be possessed by the farmers. They included milch animals, drought animals, young stock, goats and poultry. The average possession of these for the different size categories of farmers both in terms of numbers as well as value indicating the proportion of the investment to the total are shown in Table 5.17.

Of the total investment of Rs.1576.03 on an average on livestock, Rs.1161/- was on milch animals which is 73.67 per cent. The average number of milch animals was 0.88. The investment on drought animals was 123.50. Investment on young stock constitutes 9.68 per cent of the total investment.

Among the various size groups, the highest number of milch animals were observed in S₄ and the lowest in group S₁. The value of milch animals was the highest for group S₃ amounting to Rs.1309.00.

Poultry were found to be the next important item of investment by the farmers. On an average each family possessed 4.58 birds, which accounted for 5.80 per cent of the total investment. Generally, the number of birds as well as the total investment on them was found to have a direct relationship with the size of the farm.

Tools, implements and machinery

Investment on tools, implements and machinery was Rs.1851.37 per farm and amounted to Rs.1508.25 per hectare on an average. This item formed only 0.46 per cent of the total assets. A break up of the total investment on tools and implements for the different size groups are shown in Table 5.19. Tools included items like spade, pick axe, crow bar, etc. and temporary items like baskets, mats, ropes, etc.

Investment on pumpset constituted the major part of the total investment - 90.60 per cent on this category of investment. This amounted to Rs.1677.40 per farm and Rs.1366.52 per hectare on an average. The proportion of

Percentage to total investment	100.00	100.00	100.00	100.00	100.00	100.00

investment of pumpsets to total expenditure for tools, implements and machinery was the highest in S_2 (92.82 per cent) and the lowest in S_1 (83.24 per cent).

The proportion of expenditure on temporary items was the highest in S_1 (11.25 per cent), the average being 3.58 per cent.

Tools and implements constituted 3.12 per cent of total investment for tools, implements and the machinery. The proportion was highest in S_1 (5.51 per cent) and lowest in S_2 (2.23 per cent).

Investment on sprayers accounted for 2.70 per cent of the total expenditure on tools, implements and machinery. This amounted to Rs.49.95 per farm and Rs.40.69 per hectare on an average.

Table 5.20 presents the distribution of tools, implements and machinery among the income groups. The proportional expenditure to the total expenditure on various items was found to be decreasing with increase in income for pumpsets and temporary items. But expenditure on sprayers was found to increase with increase in income.

Shares in co-operatives

Another item of investment was shares owned by the farmers in the co-operative societies. This item accounted

for only a meagre 0.01 per cent of the total investment. The distribution for the various size and income groups are shown in Tables 5.21 and 5.22 respectively. In both the income groups and size groups bulk of the shares owned by farmers were in service co-operative societies. The total value of shares possessed was seen to be for Rs.6005/- only - Rs.4155 in service co-operative societies, Rs.1050/- in milk co-operative societies and Rs.800/- in other types of societies.

Economics of Farm Business

CHAPTER VI

ECONOMICS OF FARM BUSINESS

Farm holdings in the area by and large are small. Each farmer was found to possess more than one fragment, consisting of wet lands and garden lands. This fact was reflected in the cropping pattern in the sample holdings. Wet lands were generally cultivated with paddy. It was seen that garden lands are put under a variety of crops such as coconut, arecanut, banana, cashew, pepper, etc. in different combinations. The practices followed for cultivation of various crops remain more or less the same in Irinjalakkuda Block. An account of the cultivation practices followed, the cost of cultivation of different crops and profitability of different crops are given in this part.

PADDY

Paddy is grown in two seasons mainly, the Mundakan season which starts by August and Pancha from January. Generally it is observed that majority of the cultivators grow paddy only during the Pancha. For both these seasons the cultivation practices remain more or less the same with slight variations to adjust to the prevailing climatic conditions. Paddy cultivation is concentrated on the banks of Karuvanneer river and in areas referred to as 'Kole lands'

which remain submerged under water for almost six months in an year.

In areas where water level is comparatively low and where the water recedes around August, two crops are made possible - Mundakan and Puncheda. In other areas only the puncheda crop is possible.

At the end of the Puncheda crop, after harvest, the lands are generally ploughed once - partial ploughing - and left to water inundation.

Cultivation operation for Mundakan paddy starts soon after the water recedes, by August. Fields are ploughed, puddled and levelled to attain required tilth. Land preparation is accomplished by ploughing using bullocks or tractors or by digging up the land. Puncheda paddy is seen cultivated both in the areas where mundakan is grown as well in lands which remain under water even during the months of June to December. In such areas where Puncheda crop is raised land preparation is effected similarly. In certain parts of the Block, namely Karuvanneer, cultivation of paddy is in lands which are dewatered.

Seeding is through both broadcasting as well as transplanting. Both high yielding and local varieties were cultivated. The seed rate for broadcast is seen to be 80-100 kg per hectare while transplanting it is around 40-50 kg per hectare.

Farmers do not treat the seeds before sowing. Seedlings to be transplanted are raised in separate nurseries and are transplanted after about 20-25 days in nurseries.

Cowdung is the organic manure commonly applied. Ash and green leaf are seen used wherever it is available. These are given as basal doses along with ploughing - preparatory cultivation. Chemical fertilizers are applied by majority of the farmers both as basal doses and top dressing.

Handweeding is the common practice to control weeds. Generally two weedings are given. Plant protection chemicals of different varieties are used to control pests and diseases. The application of pesticides are more for Punched than for Mundakan.

Harvesting is by cutting at the base of plants and they are bundled and transported, threshed and cleaned. Women are generally employed for these operations. Workers are paid cash wages except for harvest where payments are made in kind.

A. Area under paddy

Both high yielding and local varieties were cultivated. Eightythree farmers of the sample were found to cultivate paddy during punched - fortyeight of them high yielding varieties and thirtyfive cultivated local varieties. The total area under the high yielding varieties of paddy was 26.87 hectares while that under local varieties was 27.57 hectares.

For Mundakan paddy, the average area under high yielding varieties per farm was 0.59 hectare and for local varieties it was 0.78 hectare. The area under traditional varieties was found to be 32.20 per cent more than that of high yielding varieties. The distribution is presented in Table 6.1.

The average area under high yielding varieties of paddy per farmer in Puncha was 0.56 hectare while that for local varieties 0.79 hectare. When distributed according to different holding size groups the area under paddy was found to increase with the size of the farm both for high yielding varieties and local varieties. Among income groups though a similar trend was observed for local varieties, it was not seen for high yielding varieties. The aggregate area under local varieties in Puncha was found to be 41.07 per cent more than that for high yielding varieties. The distribution is given in Table 6.2.

The cost per hectare of high yielding varieties during Mundakan season on an average was found to be Rs.4186.60 (as shown in Table 6.3). The highest cost was recorded by S₃ (Rs.4513.00) which was 7.80 per cent higher than the average cost and 25 per cent higher than the lowest cost recorded by S₄ (Rs.3610.32). For the local varieties the average cost was found to be 22.18 per cent lower (Rs.3426.70) than that of the high yielding varieties. The highest cost was found to be Rs.3549.23 in S₁, which was 3.58 per cent higher than

Table 6.3. Total cost of cultivation per hectare of paddy (Mundakan)

Table 6.4. Total cost of cultivation per hectare of paddy (Puncha)

(in rupees)

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
a) High yielding varieties	5929.20	5337.42	5237.96	4871.27	4647.40	4959.11
b) Local varieties	5924.51	4627.41	4312.07	4831.49	4345.43	4498.27
Income groups	I ₁	I ₂	I ₃	I ₄	I ₅	Average
a) High yielding varieties	5116.11	4951.06	4980.13	4931.28	4914.38	4959.11
b) Local varieties	4506.91	4476.45	4588.05	4033.52	4511.18	4498.27

the average and 12.14 per cent higher than the lowest recorded in S_3 (Rs.3164.98).

Among the income groups the cost of cultivation per hectare for HYVs was found to be increasing with an increase in income.

The total cost of cultivation per hectare of paddy for the Pancha both for high yielding varieties and local varieties for the different classes and groups are represented in Table 6.4. The average cost incurred for the high yielding varieties was Rs.4959.11, while that for local varieties it was Rs.4498.27 which was 1.24 per cent less. It can be noted from the table that the cost of cultivation for the different size groups both for HYVs and local varieties were found to decrease with increase in area. The highest cost for HYVs was recorded by S_1 (Rs.5929.20) which is 19.56 per cent more than the average, while the lowest recorded by S_5 the largest size group (Rs.4647.40) which is 27.58 per cent less than the cost for S_1 . The average cost of cultivation of local varieties was Rs.4498.27. In this case the cost for S_1 was found to be 31.70 per cent more than the average and 37.39 per cent more than the lowest cost per hectare incurred by S_5 . It may also be noted that the cost per hectare for the lowest size group which had only a tiny area of 0.13 hectare under paddy remained almost the same for both HYVs and local varieties. The higher costs in the lower size groups appear to be

due to certain indivisibilities, particularly in the employment of wage labour.

The total cost per hectare among the various income groups for the high yielding varieties showed decreasing trend with increase in income.

An inputwise split up of the average cost of cultivation per hectare of paddy for both the high yielding varieties and the local varieties for Puncheda and Mundakan are represented in Table 6.5. It is clear from the table that the bulk of the total cost was incurred on hired human labour, which accounted for around 30 per cent of the total. Rental value of land assumed next in the order of importance, also accounting for 25 to 30 per cent of the total cost. Use of manures and fertilizers put together accounted for 8 to 13 per cent of the total cost.

The cost of cultivation distributed between the various operations is attempted to and is presented in Table 6.6. Among the various operations the largest proportion of cost to the total cost was incurred on seed materials and sowing - around 18 per cent on an average. Harvesting constituted about 15 per cent. Expenditure on preparation of land accounted for about 10 per cent to the total cost. The expenditure on fertilizers in the case of Puncheda high yielding varieties was three times more than that for Mundakan high yielding varieties.

	Total cost	4959.11 (100.00)	4498.97 (100.00)	4186.60 (100.00)	3426.70 (100.00)

(Figures in parentheses are percentages to total)

But for plant protection, expenditure during Punched was double the expenditure incurred during Mundakan. No cost was incurred on irrigation for the Mundakan as it is a rainfed crop.

In computing cost C imputed rental value of land was also accounted for, which cannot be considered as a true representation of the actual cost incurred by the farmers. So a split up of cost of cultivation on the basis of total cost excluding the rental value of land was worked out and is shown in Table 6.7. According to this the extent of hired human labour during Punched season was to the order of about 40 per cent for both the high yielding and local varieties. For Mundakan high yielding varieties more than 50 per cent of the expenditure was on hired labour and 15.85 per cent of the expenditure was on seed material. Family labour constituted only 1.29 per cent of the total cost. The respective proportion of expenses for local varieties were 45.51, 17.21 and 0.62.

Among the various operations seed materials and sowing and harvesting accounted for the bulk of the cost. The proportion of expenditure on seed materials and sowing was the highest for local variety Mundakan accounting for 29.39 per cent, followed by high yielding Mundakan varieties (28.81 per cent), Punched local varieties (20.84 per cent) and Punched high yielding varieties (18.41 per cent).

(Figures in parentheses are percentages to total)

For harvesting the proportional expenditure was 28.78 per cent for Mundakan high yielding varieties, 23.55 per cent for local varieties in Mundakan season 20.91 per cent for Punched HYVs and 18.80 per cent for Punched local varieties. The cost of fertilizers and its application was the highest for HYVs punched Rs.595.10 accounting for 16.23 per cent of the total cost. The proportion of the same for the local variety Punched was 10.39 per cent (Rs.353.57). For the Mundakan, this operation accounted for 7.66 per cent of the total cost (Rs.184.63) for local varieties while 6.21 per cent for HYVs (Rs.177.36). The proportion expenditure to total cost for manures and manuring was found to be higher for Mundakan in general accounting for Rs.218.52 (9.06 per cent) for the local varieties and Rs.234.71 (8.20 per cent) for the HYVs. The expenditure on this item for Punched local varieties was Rs.159.05 (4.67 per cent) and HYVs Rs.98.60 (2.69 per cent). The cost for preparing the land was the highest for Punched local varieties Rs.599.65 (17.62 per cent) followed by HYV Punched Rs.528.76 (14.41 per cent). For the Mundakan this item accounted for Rs.366.86 for local varieties, Rs.328.17 for high yielding varieties. Irrigation, an operation only for the Punched crop accounted for little more than 9 per cent for both high yielding and local varieties. The information is presented in Table 6.8.

Table 6.8. Cost of cultivation per hectare of paddy excluding rental value of land (operationwise)

(in rupees)

Sl. No.	Operations	Puncha		Mundakan	
		HYV	LV	HYV	LV
1	Preparation of land	528.76 (14.41)	599.65 (17.62)	328.17 (11.47)	366.86 (15.21)

	Total cost	3668.42 (100.00)	3403.12 (100.00)	2860.60 (100.00)	2411.21 (100.00)

(Figures in parentheses are percentages to total)

Resource use in paddy cultivation

a) High Yielding Varieties during Mundakan season

In this, the use of family labour was found to be decreasing with increase in size in the case of high yielding varieties. The hired man labour use was the highest in S₁ (212.50 man hours) but the hired female labour was the highest in S₅ (1065 hours), the average being 72.72 hours and 1032.27 hours respectively. The involvement of family labour was of the order of 15.51 in the case of male labour and only less than one per cent in the case of female labour. The utilization of bullock and tractor shows that bullock labour was the highest in S₁. This was the lowest in S₂ where the use of tractor was higher. The respective averages were 19.31 and 1.96 hours.

Use of seeds also showed variation - the highest rate in S₃ (151.78 kg) which is 54.12 per cent higher than the lowest rate used (98.48 kg) in S₁, the average use being 130.74 kg as against the recommended rate of 80-100 kg for broadcasting.

It can be seen from Table 6.9 that the use of fertilisers was much below the recommended dose. The quantities applied by the farmers as percentages of recommended rate, ~~7.15%~~ in the case of N, P and K were 83.21 per cent, 71.86 per cent and 61.34 per cent respectively on an average. The lowest

Table 6.9. Use of resources per hectare (Mandakan high yielding varieties - size groupwise)

Groups	Unit	S ₁	S ₂	S ₃	S ₄	S ₅	Average
Family labour (hrs)							
Men		97.50	12.50	20.00	45.00	7.50	13.35

Fertilisers (kg)							
Nitrogen		19.88	-	14.00	16.60	8.08	11.75
Phosphorus		19.88	-	8.88	15.18	7.25	9.85
Potash		19.88	-	23.85	8.75	8.70	13.53

nitrogen use was in S₁ (6.45 kg) which is only 13.50 per cent of the recommended dose. Even the highest level used (28.75 kg in S₄) was only 41.07 per cent of the recommendation. The highest quantity of phosphatic fertilizers used was 17.95 kg in S₂ just above 50 per cent of the recommendation. In the case of potassic fertilizers only in S₄ the use was found to be almost on par with the recommended dose and in all the other groups it was very low.

Among the income groups (as per Table 6.10) no farmer in I₂ was cultivating high yielding varieties of paddy. Family labour use was found to be decreasing with the increase in income. In all the income groups the use of fertilizer was below the recommended dose.

b) Local Varieties during Mundakan season

The use of family labour was found to be very low for Mundakan local varieties. The use of hired female and male labour was found to be almost the same among the groups, the averages being 49.35 hours and 925.72 hours respectively. The bullock labour was found to be the highest in S₁ and tractor use highest in S₃. The respective overall averages were 20.15 hours and 4.29 hours.

Seed rate was found to vary widely among the holding size groups. The average seed rate was 119.84 kg. As stated

Table 6.11. Use of resources per hectare (Mundakan-local varieties size groupwise)

Groups	Unit	S ₁	S ₂	S ₃	S ₄	S ₅	Average

Potash		-	-	23.10	16.15	8.25	14.00

earlier no group was found to apply fertilizers upto the recommendation. The farmers in S₁ are found to be applying lower quantities of N, P and K. The average use of fertilizer was 13.5, 10.29 and 14 kg of N, P and K respectively. The details are furnished in Table 6.11.

Table 6.12 shows the use of resources among the income groups. The use of family labour was found to be decreasing with an increase in income, in general. Though hired female labour did not show much variation, hired male labour was found to vary much among the groups. It was 7.5 hours in I₂ and 72.5 hours in I₄ - i.e., about 10 times. The average worked out to 49.35. Bullock labour utilization was almost the same, but tractor use differed much. In the first two income groups no tractor labour was used. The average tractor use was 4.29 hours. The seed rate did not vary much. In the first two income groups fertilizers was not used at all.

c) High Yielding Varieties during Purncha season

Table 6.13 shows details of resource use per hectare for HYVs during Purncha. On an average 81.53 hours of male labour and 960.76 hours of female labour was used. The proportion of family labour to total labour was to the tune of 20.25 per cent in the case of male labour and only 1.08 per cent in the case of female labour. From the table it can be noted that the per hectare employment of family labour - both

male labour and female labour was found to decrease with an increase in the size of the holdings. The quantum of employment of hired labour - male as well as female - per hectare did not show any constant pattern. Use of bullock pairs also showed a decreasing trend with the increase in the size of the farm. The employment of tractor power was higher in S_3 and S_4 than the other groups - the average being 4.93 hours.

With regard to the quantity of seeds used per hectare, the groups showed not much difference, the average quantity of seeds used being 127.87 kg per hectare.

On an average 51.37 kg of N, 27.25 kg of P_2O_5 and 49 kg of K was used as against the recommended dose of 70 kg N, 35 kg P_2O_5 and 35 kg K.

The per hectare use of fertilizers in the different holding size groups was found to decrease with an increase in the size. In group S_2 though the application of nitrogen was the highest (62.73 kg per hectare), it was 9.84 per cent less than the recommended dose. The application of nitrogen was found to be the lowest for group S_4 (40.20 kg per hectare). Considerable variation was noticed among holding size groups in the use of phosphatic fertilizers as well as potassic fertilizers though in the later case the rate of use was even higher than the recommendation.

Table 6.13. Use of resources per hectare (Puncha-high yielding varieties size groupwise)

Groups	Unit	S ₁	S ₂	S ₃	S ₄	S ₅	Average

Nitrogen		52.90	54.80	33.48	53.98	56.98	51.37
Phosphorus		33.55	34.03	22.55	23.33	26.20	27.25
Potash		54.80	27.68	42.50	70.70	51.63	49.00

The utilization of family labour in various income groups showed similar trend as that of the holding size groups as shown by Table 6.14. Use of hired human labour was not seen to vary much with increase in income - it was around 65 man hours in the case of male labour and around 950 hours in the case of female labour. The use of bullock labour showed a decreasing trend with increase in income, the average being 34.40 hours. The quantity of seeds used did not differ much between the different income groups.

None of the groups were found to be using the recommended dose of nitrogenous fertilizers. Moreover, there was considerable variation in fertilizer use among income groups. It is therefore reasonable to assume that level of farming income did not influence fertilizer use. Farmers in I₅ found to be using the largest quantity of nitrogenous fertilizer, 56.98 kg which is also less than the recommended quantity.

d) Local Varieties during Purncha season

The use of the resources - labour, seed material and fertilizers for purncha local varieties are shown in Table 6.15. Here also decreasing use of family labour was seen with regard to male and female labour in the increase of holding size. Hired male labour use also decreased with increase in the size. Hired female labour remained almost the same

Table 6.15. Use of resources per hectare (Punjab-local varieties size groupwise)

Groups	Unit	S ₁	S ₂	S ₃	S ₄	S ₅	Average
Family labour	hrs						
Men		67.50	7.50	10.00	15.00	5.00	8.77
Women		120.00	12.50	5.00	12.50	5.00	8.59
Hired human labour	hrs						
Men		130.00	70.00	67.50	80.00	65.00	69.82
Women		1037.50	1042.50	937.50	1062.50	1017.50	1020.68
Total human labour	hrs						
Men		197.50	77.50	77.50	95.00	70.00	78.59
Women		1157.50	1055.00	942.50	1075.00	1022.50	1029.27
Bullock labour	hrs	60.00	67.50	37.50	42.50	42.50	42.21
Tractor labour	hrs	-	1.17	3.56	0.42	6.23	3.99
Seeds	kg	136.38	140.15	112.40	109.33	136.43	127.85
Fertilizers:	kg						
Nitrogen		43.55	36.23	25.98	32.08	26.50	28.91
Phosphorus		-	12.33	14.38	20.38	17.63	17.10
Potash		-	15.65	14.98	31.75	33.88	28.78

except in S₃ where it was the lowest amounting to 937.5 hours - the average being 1020.68 hours. While bullock labour decreased with holding size, tractor use increased with increase in size of holding. Utilisation of seeds per hectare showed little variation among groups - the average use worked out to 127.85 kg.

Only farmers in the smallest size group was found to be using the recommended dose of nitrogenous fertilizer of 40 kg per hectare. The average use of nitrogenous fertilizer was 28.91 kg and that was 27.73 per cent less than the recommended dose. The average use of phosphatic fertilizer worked out to 17.10 kg, which was 14.50 per cent lower than the recommended dose. In S₁ no farmer was seen using phosphatic and potassic fertilizers for local variety paddy during pancha. With regard to potassic fertilizers, the average use was 43.90 per cent higher than the recommended dose of 20 kg per hectare.

Among the various income groups (Table 6.16) the male family labour use was the highest in the first income group (25 man hours) and female family labour highest in I₂ (25 hours). The averages were 8.77 and 8.59 hours respectively. Hired male labour was the highest in I₄ (107.5 hours) and female labour in I₁ (1205 hours). The respective averages were 69.82 hours and 1020.68 hours. While tractor power was

Table 6.16. Use of resources per hectare (Puncha-local varieties income groupwise)

Groups	Unit	I ₁	I ₂	I ₃	I ₄	I ₅	Average
Family labour	hrs						
Men		25.00	10.00	10.00	-	2.50	8.77

Potash		8.40	15.65	38.45	45.00	27.23	28.78

found to be increasing with the increase in income, the bullock labour was found to decrease with increase in income - the average of each being 3.99 hours and 42.21 hours respectively. Seed rate remained almost the same among the different income groups.

None of the groups were found to use nitrogenous fertilisers upto the recommended dose. The lowest level of use was in I_4 (23 kg) which is 42.50 per cent lower than the recommended dose. The use of phosphatic fertilisers was very low (9.43 kg) in I_1 and higher than the recommended dose in I_3 (26.58 kg). In I_1 , the use of potash was also very low (8.40 kg) and in I_4 it was more than double (45 kg) the recommended dose of 20 kg.

Yield and output of paddy per hectare

a) High Yielding Varieties during Mundakan season

The holding size wise and income group wise yield and output of high yielding varieties is given in Table 6.17. Average yield was found to be 33.58 quintals. Yield shows much difference among the size groups. It was found to be the highest in S_3 (39.99 quintals) and the lowest in S_1 (21.08 quintals). Byproduct contributes 19.39 per cent of the total receipt. The contribution of main product to total receipt was found to be the highest in S_2 (82.92 per cent). Total receipt was recorded to be the highest in S_3 (Rs.7885.20)

**Table 6.17. Yield and output of paddy per hectare -
Mundakan high yielding varieties**

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
Yield in quintals	21.08	30.34	39.99	26.25	34.44	33.58

(Figures in parentheses are percentages to total)

which is 80.33 per cent higher than that of the lowest in S_1 (Rs.4372.73). The yield and output for the income groups are also shown in Table 6.17. The yield and output showed no consistent relationship.

b) Local Varieties during Mundakan season

Table 6.18 shows the yield and output of local varieties of paddy cultivated during mundakan. The average yield was 23.79 quintals per hectare. Yield was found to be the highest in S_2 (24.23 kilograms) and the lowest in S_1 (21 quintals). The proportion of main product and byproduct to total returns was found to be 78.24 per cent and 21.76 per cent, their respective value being Rs.3962.80 and Rs.1101.82. The proportion of value of main product to total receipt was found to be the highest in S_5 (79.69) and the lowest in S_4 (74.83 per cent). On an average the total output was found to be Rs.5064.62.

The various income groups did not show any constant pattern with regard to yield - the highest yield was in I_3 (28.52 quintals) and the lowest in I_1 (19.38 quintals). The contribution of byproduct to total returns varied from 25.55 in I_4 to 20.33 in I_2 . The total returns also showed wide variation among the income groups - the highest receipt was in I_3 (Rs.5994.56) and the lowest in I_1 (Rs.4165.38).

Comparing the high yielding varieties with local

(Figures in parentheses are percentages to total)

varieties cultivated during the Mundakan season it can be seen that high yielding varieties gave 40 per cent higher yield than the local varieties. Proportional contribution of byproduct to total output was 19.39 per cent for high yielding varieties and 21.76 per cent in the case of local varieties. Even though the yield difference was 41.15 per cent, the total returns was 30.91 per cent higher in high yielding varieties than the local varieties. This difference can be attributed to the higher price of the local varieties for both main product and byproduct.

Among size groups, the proportional contribution to total returns of byproduct was found to be higher in the case of local varieties than the high yielding varieties, it is of the order of 17 to 22 in high yielding varieties while in local varieties 20 to 25 per cent.

e) High yielding varieties during Pancha season

Information on yield and output of pancha high yielding varieties of paddy, both size groupwise as well as income groupwise is presented in Table 6.19. The average yield per hectare was found to be 33.82 quintals which was valued at Rs.5275.56. Both yield and output of paddy were the highest for the farmers in S₁ (35.67 quintals and Rs.5423.66) and

**Table 6.19. Yield and output of paddy per hectare -

b) Byproduct (Rs)	1348.03 (21.32)	1070.65 (18.19)	1025.71 (16.19)	1345.01 (20.29)	1185.41 (17.54)	1177.92 (18.25)
Total receipt	6321.83 (100.00)	5886.05 (100.00)	6335.77 (100.00)	6629.07 (100.00)	6757.03 (100.00)	6453.48 (100.00)

(Figures in parentheses are percentages to total)

the lowest in S_7 . The contribution of byproduct to total output was 18.25 per cent on an average. The contribution of main product to the total output is seen to decrease with increase in the size of the holdings. On an average the income from byproducts amounted to Rs.1177.92 per hectare.

Among the income groups the proportional contribution of main product to total output was found to be the highest in I_3 (83.81 per cent). Total output was found to increase with increase in income except in I_2 (Rs.5886.05) which had the lowest, the highest value being Rs.6757.03 in I_5 .

d) Local varieties during Purnha season

Table 6.20 shows the yield and output of the local varieties. On an average it was 25.89 quintals per hectare - 30.63 per cent less than that recorded by the high yielding varieties. Yield was found to be decreasing with increase in holding size. Highest yield was recorded by S_1 (33.26 quintals) which was 28.47 per cent higher than the average and 37.89 per cent higher than the lowest yield of 24.12 quintals which was obtained by S_5 . This higher yield may be due to natural improvements in local varieties. The main product-byproduct ratio in its contribution to total returns was found to be 3:1, their values being Rs.4144.96 and Rs.1334.22. Total receipt was the highest in S_1 (Rs.7001.29)

Table 6.20. Yield and output of paddy per hectare - Punccha local varieties

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
Yield in quintals	33.26	26.66	24.27	30.27	24.12	25.89
Output:						
a) Main product (Rs)	5496.21 (78.50)	4264.31 (75.15)	3941.87 (73.88)	4842.76 (78.68)	3858.96 (74.64)	4144.96 (75.65)

Total receipt	7001.29 (100.00)	5674.10 (100.00)	5335.70 (100.00)	6155.30 (100.00)	5170.35 (100.00)	5479.18 (100.00)
Income groups	I ₁	I ₂	I ₃	I ₄	I ₅	Average
Yield in quintals	27.10	26.77	26.27	26.25	24.28	25.89
Output:						
a) Main product (Rs)	4318.57 (77.11)	4305.07 (75.41)	4211.21 (75.31)	4200.00 (79.25)	3884.93 (74.74)	4144.96 (75.65)
b) Byproduct (Rs)	1281.97 (22.89)	1404.10 (24.59)	1380.49 (24.69)	1100.00 (20.75)	1312.79 (25.26)	1334.22 (24.35)
Total receipt	5600.54 (100.00)	5709.17 (100.00)	5591.70 (100.00)	5300.00 (100.00)	5197.72 (100.00)	5479.18 (100.00)

(Figures in parentheses are percentages to total)

and the lowest in S_5 (Rs.5170.35), the difference of the order of 35.41 per cent.

Among the income groups, the yield and the total receipt were found to decrease with increase in income. Yield was 27.10 quintals in I_1 , while it was 24.28 quintals; 11.61 per cent lower, in I_5 . The total receipt was the highest in I_2 (Rs.5709.17) which was 9.84 per cent higher than the lowest recorded in I_5 (Rs.5197.72).

Comparing the yield of high yielding varieties with local varieties during the pancha season it was found that the yield was 30.63 per cent higher in the former than the later. The contribution of the byproduct to total receipt was 18.25 per cent in the high yielding varieties while it was 24.35 per cent for local varieties. Even though the yield difference was 30.63 per cent, the difference in the value of main product between these varieties was only 27.28 per cent, the reason was the higher price realised for local variety paddy. The value of total output was only 17.78 per cent higher in the high yielding varieties than the local varieties.

Income measures

Cost of production of paddy

The cost of production per quintal of paddy was worked out, both for pancha as well as for mundakan and are represented

in Tables 6.21 and 6.22. The cost C includes the value of paddy paid as wages for harvest. The grain yield recorded also includes the quantity given as wages for the harvest. Hence deduction of the value of grains attributed to harvest and the quantity of grain given as wages from the yield are done for adjustment. From the resultant cost, the cost of producing the grains was arrived at by subtracting the value of byproduct from the total cost. The cost per quintal was worked out on the total cost including rental value of land and for excluding rental value. To obtain the cost for producing paddy, excluding the rental value of land, the amount of rental value accounted by grain alone was deducted.

The cost of production of high yielding varieties on an average during Mundakan season was found to be Rs.73.13 at cost C and exclusive of rental value of land, it was only Rs.55.51.

The cost of producing local varieties was found to be higher than that of high yielding varieties (Rs.86.21) at cost C and Rs.47.33 at cost excluding rental value on an average.

For Pancha high yielding varieties the cost of production per quintal was found to be Rs.104.29 at total cost. But exclusive of rental value of land, it was only Rs.67.78 per quintal of paddy. The cost of production was found to be

Table 6.21. Cost of production of paddy per quintal - Mundakan

(in rupees)

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average

At cost excluding rental value	74.52	68.71	75.59	62.14	88.86	77.44

decreasing with increase in the size of holding. At total cost excluding rental value of land, it varied from Rs.102.36 in the smallest holding size group to Rs.55.27 in the largest holding size group. No consistent relationship was found between gross farming income and cost per quintal of paddy.

For local varieties the cost per quintal was found to be higher than that of high yielding varieties. On an average the cost per quintal amounted to Rs.115.30 at total cost and Rs.77.44 at total cost excluding rental value of land. The cost was found to be decreasing with increase in size of holding except in the highest holding size. As in the case of HYVs, here also size of family income did not show any influence on cost per quintal.

Averaging the cost of production for both the seasons, the cost of production of high yielding varieties of paddy amounted to Rs.98.76 per quintal at cost C and it was only Rs.51.70 at total cost excluding rental value. For local varieties the cost of production was found to be Rs.105.69 at cost C and Rs.63.02 at total cost excluding rental value of land.

b) Income from paddy cultivation

It is commonly believed that the cultivation of paddy these days results in loss. It will therefore be of interest to understand the returns from cultivation. There are

different measures which can be used to evaluate farm profits. The income measures that are used in this study are (i) Net income at cost C, (ii) Net income excluding rental value of land, (iii) Farm business income, (iv) Family labour income and (v) Farm investment income. The benefit-cost ratio was also worked out.

Table 6.23 presents the various income measures worked out for Mundakan high yielding varieties. Profit at all cost levels was found to be the highest in S_3 and lowest in S_1 . Net income on an average at cost C was found to be Rs.2443.38 and at cost excluding rental value, Rs.3769.38. Average farm business income, family labour income and farm investment income worked out to Rs.3830.21, Rs.2480.25 and Rs.3793.34 respectively. On an average, the benefit-cost ratio at cost C was found to be 1.58. The highest ratio was in S_3 (1.75) followed by S_5 (1.63), S_4 and S_2 (1.44 each) and the lowest in S_1 (1.02). On an average the benefit-cost ratio at cost excluding rental value of land was worked out to 2.32.

Among the income groups, profit was found to be the highest in I_4 and the lowest in I_1 at all cost levels. The benefit cost ratios were 1.75 and 1.32 for I_4 and I_1 respectively at cost C.

Table 6.24 shows profit at various cost levels for Mundakan local varieties. The net income at cost C on an

b) cost excluding rental value of land	2.09	1.74	2.36	2.40	1.84	2.10

average worked out to Rs.1637.92. The profit was found to be the highest in S_3 and the lowest in S_1 . Rs.2692.40, Rs.1652.95 and Rs.2677.37 were the farm business income, family labour income and farm investment income respectively, on an average. The benefit-cost ratio at cost C was 1.48 on an average. The highest ratio was recorded in S_3 (1.71) followed by S_4 and S_5 (1.50), S_2 (1.41) and S_1 (1.28). The benefit-cost ratio at cost excluding rental value of land on an average was worked out to 2.10.

Among the income groups profit was found to be the highest in I_3 and the lowest in I_5 at all cost levels. The benefit-cost ratio was found to be the highest in I_4 (1.62) and the lowest in I_2 (1.29).

The high yielding varieties were found to be more profitable than the local varieties at all cost levels, comparing the average values. But in S_1 , S_4 and I_3 the LVs were found to be more profitable than the HVs.

In Table 6.25 is shown the different measures of profit cultivating high yielding varieties during Purncha both size groupwise and income groupwise as well as the benefit-cost ratios. Profit at all cost levels was found to be the lowest in S_1 and the highest in S_5 . Net income at cost C was found to be Rs.1494.37 per hectare on an average. Net income was found to be the lowest in S_1 (Rs.415.26) and the

a) total cost	1.24	1.19	1.27	1.35	1.37	1.30
b) cost excluding rental value of land	1.64	1.56	1.71	1.84	1.90	1.76

highest in S₅ (Rs.1842.43) which was 3 times higher than S₁ and 23.29 per cent higher than that of the average. Net income at cost excluding rental value was found to be Rs.2785.06 on an average. In general, the size groups show an increasing trend with regard to the various income measures. The average farm business income, family labour income and farm investment income were found to be Rs.2863.93, Rs.1549.28 and Rs.2809.02 respectively. The benefit-cost ratio was generally found to increase with increase in size. The average value was recorded to be 1.3, the highest in S₅ (1.40) and the lowest in S₁ (1.07).

Among the income groups the profit at all cost levels was found to be the highest in I₅ and the lowest in I₂. Benefit-cost ratios did not show any consistent pattern.

The various income measures for the cultivation of local varieties during Purncha is given in Table 6.26. The net income at cost C was Rs.980.91 on an average. The profit at all cost levels was found to decrease with an increase in size with the exception of S₄. The net income was found to be the highest in S₄ (Rs.1323.81) which was 34.96 per cent higher than the average and 60.48 per cent higher than the lowest recorded by S₅ (Rs.824.92). Average profit at total cost excluding rental value of land was Rs.2076.75 per hectare. The farm business income and family labour income worked out to Rs.2135.58 and Rs.1016.47 respectively. Benefit-cost ratio

Table 6.26. Measures of income and benefit-cost ratios for local varieties - Pancha

(in rupees)

a) total cost	1.24	1.28	1.22	1.31	1.15	1.22
b) cost excluding rental value of land	1.65	1.71	1.61	1.78	1.50	1.61

was found to be the highest in S_4 (1.27) followed by S_3 (1.24), S_2 (1.23), S_5 (1.19) and S_1 (1.18) which was the lowest. Among the income groups, the net income at cost C was found to be the highest in I_4 (Rs.1266.48) and the lowest in I_5 (Rs.686.54).

Comparing the local and high yielding varieties in Puncha, the profit was found to be lesser in the case of local varieties than the high yielding varieties. The net income was found to be 52.35 per cent higher for HYVs. Benefit-cost ratio at cost C was 1.22 in the case of LVs as against the HYVs with benefit-cost ratio of 1.30. In all the groups excepting S_1 and I_2 the high yielding varieties were found to be more profitable.

The high yielding varieties of paddy grown during the Mundakan season was found to fetch more profit per hectare than that of puncha. The net profit at cost C was 63.51 per cent higher during Mundakan. The reason may be attributed to the higher cost of cultivation during Puncha mainly on account of irrigation, fertilizers and plant protection expenses. The benefit-cost ratio at cost C was worked out to 1.58 in Mundakan as against 1.30 in Puncha.

The local varieties cultivated during Mundakan was also found to be more profitable than that of similar varieties in Puncha. The net income was found to be 66.98 per cent

higher than that of Punched. The benefit-cost ratio was 1.48 for Mundakan local varieties, while that for Punched was only 1.22.

COCONUT

Coconut is estimated to be grown in 2610 hectares in the block and is an important cash crop. Only annual maintenance is carried out for the crop.

The operations start with the onset of monsoon. The basins around each palm are cleared of weeds and opened up so as to enable application of manures and fertilizers.. Usually green leaf, wherever available, some quantity of fertilizers and ash are applied and the basins are covered.

By January, the basins are again cleared and opened so as to enable irrigation. Generally the palms are irrigated two to three times a week for about five months.

Harvesting of nuts are usually once in 45 to 60 days (fortyfive days during summer and sixty days during rainy season). In an year, there can be 7 to 8 harvests.

Area under coconut

The area under coconut in the sample as a whole was found to be 44.35 hectares on an average. The per farm area under coconut was found to be increasing with an increase in the size of the holdings as well as the income of the farmer.

Table 6.27. Area under coconut

A. Size groups	6445.77	6788.56	6206.43	6372.46	6210.54	6330.79
B. Income groups	6279.02	7151.31	5846.63	6514.37	6280.11	6330.79

The average area under coconut worked out to 0.44 hectare per farm. The table 6.27 shows the area under coconut in size groups and income groups.

A. Cost of maintenance of coconut

The cost of maintenance of coconut per hectare was worked out both inputwise as well as operationwise and is given as Appendix tables II.17 to II.20.

The average cost of maintenance was worked out to Rs.6330.79 (Table 6.28). Among the various holding size groups, the highest cost was recorded against S₂ (Rs.6788.56) which was 7.23 per cent higher than the average cost. The cost of maintenance per hectare among the size groups as well as the income groups varied and no definite trend was seen.

Among the various inputs used, manures accounted for the largest proportion of total expenditure followed by hired human labour (5.29 per cent) and irrigation (3.68 per cent). Harvesting charges accounts for about 10 per cent of the total cost. Imputed rental value of land formed the bulk of total cost which is Rs.2778.35. The inputwise cost of maintenance is given in Table 6.29.

Table 6.30 shows the operationwise maintenance expenditure of coconut. Among the different operations the expenditure was the highest on manures and manuring (11.21 per cent) followed by harvesting (10.78 per cent), irrigation

(Figures in parentheses are percentages to total)

(5.95 per cent) and intercultural operations (2.25 per cent). The expenditure on fertiliser was found to be very low (only 2.16 per cent) and on plant protection meagre (0.23 per cent).

Imputed rental value of land formed the bulk of the total cost Rs.2778.35 (43.89 per cent). The cost of maintenance excluding rental value of land was also worked out and is also given in Table 6.29. 19.20 per cent of this out of pocket expenses was on harvesting charges, 16.70 per cent on miscellaneous items and 16.61 per cent on manures. The expenditure on hired human labour, irrigation and fertilizers was 9.44 per cent, 6.57 per cent and 2.93 per cent respectively.

B. Resource use

Table 6.31 shows the utilisation of various resources among the different holding size groups. Family labour use was found to decrease with the size both for male and female labour, the average being 40.56 hours and 3.06 hours respectively. The hired male labour use was the highest in S₃ (127.5 hours) and the lowest in S₁ (82.50 hours). Hired female labour was found to be the highest in S₄ (20 hours) and the lowest in S₅ (12.5 hours). Compared with the fertilizer recommendation, the quantity of fertilizer applied was found to be far below. The quantities of N, P and K applied per hectare on an average were 5.20 kg, 6.49 kg and 17.34 kg

**Table 6.31. Resource use of coconut per hectare
(size groupwise)**

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average

Potash	5.73	49.65	2.85	69.53	6.05	17.34

which was found to only 7.65 per cent, 19.00 per cent and 12.75 per cent respectively of the recommended quantities of

CS.34:136-In income classes also family labour was found to decrease with increase in income. Among the income groups better use of fertilizer use was in I₄, 32.58 kg N, 31.88 kg P and 69.53 kg K.

C. Returns from coconut cultivation

Yield and output of coconut

The yield and output of coconut is shown in Table 6.33. The average number of nuts per hectare was found to be 9995.83. The yield per hectare was found to be the highest in S₄ (10931 nuts or 54.66 nuts per palm), which was found to be 9.36 per cent higher than the average and 26.96 per cent higher than the lowest yield obtained in S₃ (8610.59). The average main product value obtained per hectare was found to be Rs.12107.23. On an average, the proportion of byproduct value to the total output was worked out to 12.85 per cent. The total output was found to increase with increase in the size of the holding.

Among the income groups the yield was found to increase with increase in income (Table 6.34). The highest yield was recorded in I₅, which was found to be 11.65 per cent higher than the average and 31.39 per cent higher than the lowest

Table 6.33. Yield and output of coconut (Size groupwise)

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
1. Yield (numbers)

(Figures in parentheses are percentages to total)

yield recorded in I₁ (8460 nuts). The average value of byproducts per hectare was found to be Rs.1784.54. The total output was found to be the highest in I₅ (15670.13) which was 12.80 per cent higher than the average and 42.70 per cent higher than the lowest recorded in I₁ (Rs.10981.48).

D. Profitability of coconut cultivation

a) Cost of production

The cost of production of coconut for 1000 nuts was worked out and is presented in Table 6.35. Cost of production at cost C (total cost) was found to be Rs.454.85. It was found to be the highest in S₁ (Rs.530.99) and the lowest in S₄ (412.51). The cost of production at cost excluding rental value of land was found to be Rs.176.88 on an average, the highest and the lowest value being Rs.288.77 in S₁ and Rs.143.92 in S₅ respectively.

Among the income groups the unit cost was found to be the highest in I₂ and the lowest in I₃ at all cost levels.

b) Measures of income

Various income measures have been worked out and are presented in Table 6.36. The net income at cost C worked out to Rs.7560.98 on an average. The net income was found to be increasing with increase in size of holdings. The highest net income was recorded in S₅ (Rs.8761.08) which is

b) cost excluding rental value of land	2.69	2.50	4.23	3.64	4.98	3.91

found to be 15.87 per cent higher than the average value and 86.22 per cent higher than the lowest income recorded by S₁ (Rs.4704.71). All the income measures were found to be increasing with an increase in income. The benefit-cost ratio at cost C was found to be 2.19 on an average with the highest and the lowest ratios being 2.41 in S₅ and 1.73 in S₁ respectively. The benefit-cost ratio at cost excluding rental value of land worked out to 3.91, on an average.

Among the income groups profit was found to be increasing with an increase in income at all cost levels, the highest values in I₅ and the lowest in I₁. The benefit-cost ratio was worked out to 2.50 in I₅ which was the highest and 1.66 in I₂, the lowest.

ARECANUT

Compared to coconut, arecanut is cultivated only to a very limited extent and generally palms in bearing stages were seen. The maintenance operations of arecanut starts with weeding and opening up basins for manuring at the onset of monsoon. Manures and green leaf are applied in the basins and covered. During January basins are opened up again for irrigation. Sale of nuts is generally on contract. Harvesting and plant protection are carried out by the contractors. The information on area under arecanut is given in Table 6.38. The average area under arecanut was found to be 0.05 hectare.

(Figures in parentheses are percentages to total)

The area under arecanut was found to be increasing with an increase in size of holding.

A. Cost of maintenance of arecanut

The cost of maintenance per hectare worked out to Rs.4565.16 on an average. The sizewise and incomewise cost of maintenance is shown in Table 6.38, and in Appendix II.21 to 24.

The highest cost was recorded by S₄ (Rs.5303.75) and the lowest by S₅ (Rs.4302.13). Among the income groups the expenditure was the highest in I₂ (Rs.4892.12). 23.96 per cent of the total cost was accounted by manures, 14.84 per cent by hired human labour and 8.24 for irrigation. The split up of cost of maintenance inputwise is given in Table 6.39.

Cost of maintenance at total cost excluding rental value worked out to be Rs.3419.41. Manures, hired human labour and irrigation forms 31.99 per cent, 19.81 per cent and 11 per cent respectively of the total cost. Cost of maintenance split up at cost excluding rental value is given in Table 6.39, and Table 6.40.

B. Resource use

For arecanut only very limited quantities of inputs are applied. Hired labour is the foremost among them. Table 6.41 shows the labour hours employed in arecanut

Table 6.41. Resource use in arecanut cultivation per hectare

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
a) Family labour(hrs)

1) Male	85.33	271.05	325.68	192.59	304.88	266.12
ii) Female	-	-	-	-	-	-

cultivation. Family labour was found to decrease with increase in the size, the average being 108.16 hours. No female labour was engaged for arecanut cultivation. The hired labour showed wide variation among size groups, the highest being in S_5 (327.35 hours) and the lowest in S_1 (19.35 hours). The use of hired labour was found to increase with increase in size. The use of hired human labour on an average was found to be 266.12 hours.

Among the income groups also the family labour was found to decrease with increase in income. Hired labour was found to be the highest in I_5 (325.68 hours) and the lowest in I_1 (85.33 hours).

C. Returns from arecanut cultivation

a) Yield and output

The average gross income from arecanut was found to be Rs.5728.74 per hectare. Since most of the produce were sold on contract basis, the data on quantity of arecanut produced could not be ascertained. The per hectare income was found to be the highest in S_4 (Rs.8361.68) which is 45.96 per cent higher than the average and more than double the lowest value recorded by S_2 (Rs.4158.29).

In general, the output was found to increase with an increase in income. In I_5 it was found to be Rs.7641.26 which is 38.38 per cent higher than the average Rs.5728.74.

Profitability of arecanut cultivation

a) Cost of production

Due to the unavailability of data pertaining to the quantity of arecanut produced, computation of cost of production is not attempted.

b) Measures of income

Average net income at cost C worked out to Rs.1163.58 (Table 6.43). The cultivation was found to incur loss in the lowest size groups. The largest size groups were found to have higher profit than the smaller size groups. Profit at all cost levels were found to be the highest in S_4 and the lowest in S_2 . The benefit-cost ratio at cost C was found to be 1.25 on an average and at cost excluding rental value of land 1.68.

The net income at cost C was found to be the highest in I_5 (Rs.2784.06).(Table 6.44).

BANANA

Systematic planting of banana was not found common and it was planted mixed with other crops. Generally banana cultivation was seen scattered in the garden lands. Paddy lands are also put under banana at times. As a rainfed crop, planting new suckers is undertaken during April-May and wherever irrigation facilities are available the crop is

planted during August-September. No definite spacing was seen adopted. Pits are made and filled with green leaf, farm yard manure. Suckers are planted in these pits. Fertilizers were rarely applied. In a few cases where it is applied, it is given in two doses, within four months of planting. Irrigation is given twice a week by farmers who have the facilities. Plant protection measures are not adopted. By the time the plants putforth bunches they are prepped up to avoid damages. Bunches are ready for harvest in 12 to 14 months from the date of planting.

Area under banana

The total area under banana in the sample was found to be only 1.15 hectares. This crop was generally cultivated as an intercrop. Only a few farmers were cultivating it as a pure crop. The area under banana is shown in Table 6.45 for both classification.

The area under banana per farm was found to be 0.01 hectare on an average. The production of banana in this regions is not market oriented.

A. Cost of cultivation of banana

The cost of cultivation of banana for both classification is worked out in terms of rupees and is presented in Appendix II.25 to II.28.

Table 6.45. Area under banana

Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
i) Total area (in ha)	0.07	0.35	0.16	0.19	0.38	1.15
ii) Per farm area (in ha)	0.01	0.01	0.01	0.01	0.02	0.01

i) Total area (in ha)	0.14	0.23	0.32	0.13	0.33	1.15
ii) Per farm area (in ha)	0.01	0.01	0.01	0.01	0.02	0.01

Table 6.46. Cost of cultivation per hectare of banana

(in rupees)						
Size groups	S ₁	S ₂	S ₃	S ₄	S ₅	Average
	39901.05	36663.11	36413.32	34885.31	33750.42	36248.82

Income groups	I ₁	I ₂	I ₃	I ₄	I ₅	Average
	39726.01	37108.85	33158.25	32241.44	38473.98	36248.82

Table 6.46 shows the cost of cultivation at cost C. The cost of cultivation per hectare of banana on an average worked out to Rs.36,248.82. Among the holding size groups the highest cost was recorded by S₁ (Rs.39,901.05) and the lowest by S₅ (Rs.33,750.42). Among the different income groups, the highest cost was incurred by I₁ (Rs.39,726.01) and the lowest by I₄ (Rs.32,241.44).

A split up of the cost of cultivation is given in Table 6.47. Rental value of land accounted 24.87 per cent of total cost which forms major item of cost followed by manures (18.48 per cent), hired human labour (14.09 per cent) and seed material (10.18 per cent).

Among the different operations, manures and manuring accounts for 23.46 per cent of the total cost, followed by seed material and sowing 10.18 per cent, fertilizers and application (8.99 per cent), preparatory cultivation (8.80 per cent) and propping (6.90 per cent) as shown in Table 6.48.

Excluding the imputed rental value of land the cost of cultivation worked out to Rs.27235.17 per hectare of which the contribution made by manures, hired human labour, seed material and fertilizers were 24.60 per cent, 18.76 per cent, 13.55 per cent and 10.13 per cent respectively. Irrigation contributes only 1.6 per cent to the total cost of cultivation.

(Figures in parentheses are percentages to total)

The table 6.49 shows the utilization of labour - family and hired, N, P, and K in banana. On an average, the family men labour accounted for 879.02 hours. The hired male labour was the highest in S_5 (2410 hours) and the lowest in S_2 (1700 hours), the average being 2036.81 hours.

The quantities of fertilizers applied were 159.52 kg N, 169.43 kg P and 346.94 kg K as against the recommended levels of 475 kg N, 287.5 kg P and 750 kg K. The highest quantities of N and P was applied by the farmers in S_5 and the lowest quantities by those in S_1 .

Among the different income groups also the application of family labour was found to decrease with increase in income. Use of hired labour was the highest in I_5 (2600 hours).

Nitrogenous fertilizer application was the highest in I_5 (215.15 kg) and the lowest in I_2 (111.55 kg). Phosphoric fertilizer use was also found to be the highest in I_5 and the lowest in I_2 . The highest potassic fertilizer use was recorded in I_1 .

a) Output from banana

Table 6.50 shows information on value of output of banana, both size groupwise as well as income groupwise. The total output per hectare was found to be worth Rs.45068.23. The output was found to be the highest in S_1 (Rs.54147.73) and the lowest in S_3 (Rs.42430.73). The contribution of

(Figures in parentheses are percentages to total)

byproduct to total output was found to be 11.10 per cent. Among the income groups the output showed no consistent pattern.

D. Profitability of banana cultivation

b) Cost of production

Since it was difficult to collect data on the quantity of banana produced, cost of production per bunch was worked out and is presented in Table 6.51. Average cost of production amounted to Rs.13.02 per bunch at cost C. Production cost was found to decrease with an increase in size of farms - it was Rs.14.04 in S₁ and Rs.11.96 in S₅. The average cost of production at cost excluding rental value of land was worked out to be Rs.9.26 per bunch.

c) Measures of income

Table 6.52 presents the various income measures worked out for banana. The average net income at cost C was found to be Rs.8819.41. The net income per hectare was found to be the highest in S₁ (Rs.14,246.68) and the lowest in S₃ (Rs.6017.41). Income at cost excluding rental value of land was worked out to Rs.17,833.06, on an average. The highest net income at cost C was noticed in I₂ (Rs.13,160.11) among the income groups. The net income at cost excluding rental value of land was recorded to be the highest in I₅

b) total cost excluding rental value of land	1.56	1.86	1.56	1.65	1.65	1.65

(Rs.18,896.94). On an average, the benefit-cost ratio at cost C worked out to 1.24 while at cost excluding rental value of land 1.65.

COSTS AND RETURNS FROM LIVESTOCK PRODUCTION

Livestock form an important part of the economy of rural households. Dairy business is considered as a profitable enterprise and has drawn the attention of the farmers.

About 65 per cent of the sample households were found to maintain milch animals, either cows or buffaloes. Drought animals were maintained by some households, but not throughout the year. The farmers possessing large areas under paddy and with sufficient financial background, purchase bullocks whenever necessary and sell the animals after use.

The number of animals owned by the farmers are shown in Table 6.53 and 6.54.

The number of crossbred cows were found to be less than the desi ones, their respective numbers were 27 and 45. In the larger size groups and higher income groups, no farmers were found to maintain buffaloes.

Costs and returns from livestock

a) Maintenance of livestock

The maintenance costs vary with the type of animal. This was found to be different in different size and income

groups. The per day maintenance costs both during lactation period and dry period is given in Table 6.55 and 6.56. The total maintenance cost was worked out depending on the duration of lactating and dry periods.

On an average it was worked out that the number of lactating days per year in cows and buffaloes were 210 and 165 days respectively. The corresponding dry periods were 155 and 200 days respectively. The maintenance costs for lactating period and dry period were worked out at the daily rates and the annual cost of maintenance was computed.

b) Milk yield

On an average the calving interval of cows was found to be 470 days - of which 270 days in milk and 200 days dry. On an average the animals were in milk during 210 days in a year. In buffaloes the calving interval was found to be 720 days - with 300 days in milk and 420 days dry, and on an average the number of days in milk per year was 165 and the dry days were 200. The average milk yield per animal per day is presented in Tables 6.57 and 6.58 in litres per day.

The average milk yield per animal per each lactating day was found to be 4.62 litres for crossbred cows (which is lower than the potential of the crossbreds) and 2.95 litres in desi cows. The average milk yield of buffaloes were worked out to 6.67 litres per day which is also below potential.

c) Costs and returns from livestock

The costs and returns from the livestock in different size and income groups for different types of animals worked out and is given in Tables 6.59 to 6.64.

Table 6.59 shows the costs and returns from crossbred cows. It was found that since the yield obtained per animal was far below the potential for crossbred cows, the net income from crossbreds was not found to be attractive. The maintenance cost was almost on par with the gross returns leaving only a marginal profit of Rs.52.59 per farm and Rs.194.76 per animal annually.

The net income per farm was found to be the highest in S_5 (Rs.210.21) and the lowest in S_2 (less of Rs.116.54). But net income per animal was recorded to be the highest in S_1 (Rs.688.58) and the lowest in S_2 (a loss of Rs.393.31).

Among the income groups (as shown in Table 6.60) the per farm net income was found to be the highest in I_5 (Rs.155.70) and the lowest in I_2 (a loss of Rs.32.96). The net income per animal was found to be the highest in I_1 (Rs.517.69) and the lowest in I_2 (a loss of Rs.189.50).

The rearing of non-descript cows involved comparatively lesser maintenance cost per animal (Rs.1389.73) as against Rs.2490.64 in the case of crossbreds). The costs and returns

in respect of non-descript cows are represented in Table 6.61. Eventhough the milk yield was higher in crossbreds, the overall net income per animal was found to be higher in desi cows than the crossbreds. The net income per animal was found to be Rs.194.76 in crossbred cows and Rs.456.52 for desi cows.

Among the size groups, the per farm net income from desi cows was found to be the highest in S₅ (Rs.417.30) and the lowest in S₁ (Rs.59.63). But net income per animal was found to be the highest in S₅ (Rs.834.61) and the lowest in S₃ (Rs.290.05).

Among the income groups (Table 6.62) the net income per animal was found to be the highest in I₄ (Rs.964.20) and the lowest in I₅ (Rs.111.77). The net income per farm was recorded the highest in I₄ (Rs.535.66) and the lowest in I₅ (Rs.45.73).

Compared to cows, buffaloes found to provide in higher net income. The size groupwise and income groupwise costs and returns were worked out and are presented in Tables 6.63 and 6.64.

Only in groups S₁ and S₃ the farmers were found to own buffaloes. The net income per animal was worked out to Rs.777.25 in S₁ and Rs.1237.85 in S₃, the average being Rs.974.65 per animal.

Among the income groups, no farmer in I₄ was found to own buffaloes.

Net income from livestock and poultry

Table 6.65 shows the net income from livestock and poultry together, size groupwise. No maintenance charges were found incurred with regard to maintenance of goats and poultry. No purchased feed were given to them. On an average the net income was worked out to Rs.1035.97. This was found to be the highest in S₅ (Rs.1377.97) and the lowest in S₂ (Rs.682.00). Among the income groups, gross income was found to be the highest in I₄ (Rs.1821.48) and the lowest in I₁ (Rs.703.63).

FARMSTEAD ANALYSIS

A typical farm in the area of study has only a small area under cultivation. This available land is put under a number of crops - seasonals, annuals and perennials. Rearing of milch animals was also common in the area. It will be of interest to understand the pattern of income and expenditure from agriculture and allied activities.

In Table 6.67 the cropping pattern, the costs incurred, gross income and net income excluding rental value of land from the different agricultural and allied activities for

the different size groups on a per farm basis are presented. In general the area under different crops was found to increase with an increase in the size of the farm. So also the expenditure, gross income and net income.

The average expenditure per farm was worked out to Rs.6111.45, 24.13 per cent of which is on livestock including poultry. The proportional expenditure on livestock was found to be decreasing with an increase in the size of the holding. It was 49.92 per cent in S_1 , 31.31 per cent in S_2 , 31.77 per cent in S_3 , 22.83 per cent in S_4 and 14.09 per cent in S_5 . The bulk of this expenditure, 25.58 per cent was on coconut. The area under coconut is also high (0.44 hectare per farm).

On an average the gross income per farm was worked out to Rs.14,303.56, of which 17.55 per cent was contributed by livestock. It may be noted that though the proportional expenditure on livestock was 24.13 per cent, the contribution to gross income was only 17.55 per cent indicating a lower benefit-cost ratio for livestock enterprise than crop production. 43.08 per cent of gross income obtained was from coconut.

The net income at total cost excluding rental value of land per farm was found to be Rs.8192.11, of which 12.65 per cent net income from livestock and the rest from crop production. Net income was found to be the highest in S_5 Rs.18,324.78 and the lowest S_1 (Rs.2326.15).

In Table 7.7 of chapter VII, the expenditure pattern for the farmers is shown. It is seen that the average household expenditure worked out to Rs.8160.64. Assuming the farmers are to meet the entire household expenditure from the income obtained out of crops and livestock, it may require 1.21 hectares of land according to this pattern. If he has to depend solely upon net income from crops alone, then it may require 1.38 hectares of land. Only in S_4 and S_5 the net income per farm from crops and livestock is sufficient enough to meet the household expenditure. This points to the fact that while making land reform policies, the economic viability of the holdings should also be considered. Otherwise there won't be any incentive for the farmer to produce maximum from the land possessed by him and thus adversely affect production and productivity.

In S_1 the net income from farm and livestock enterprises covers only 34.42 per cent of the household expenditure, in S_2 it is 56.51 per cent and in S_3 72.40 per cent.

Table 6.68 shows the farm income, farm expenditure and net returns per hectare of land under the existing cropping pattern in the area. In general a hectare of land had 0.59 hectare under paddy (including both mundakan and puncha), 0.32 hectare under coconut, 0.04 hectare under arecanut, 0.02 hectare under various crops and 0.01 hectare each under banana, pepper and cashew.

The expenditure per hectare for crop production and livestock production on an average was worked out to Rs.4527.00 and the gross income Rs.10,595.23 leaving a net income of Rs.6068.23.

The area required to provide net income (at cost excluding rental value of land), from crops alone, sufficient enough to meet the household expenditure for various size groups were worked out and is given in Table 6.69. It can be seen that only the farmers in the largest holding size group had sufficient area under possession.

Table 6.69. Optimum land requirement under the existing cropping pattern

	S ₁	S ₂	S ₃	S ₄	S ₅	Average
1. Net farm income at cost excluding rental value of land (in rupees)	4980.00	5394.92	4845.74	5339.59	6619.85	5914.17

House hold economy

CHAPTER VII
HOUSEHOLD ECONOMY

The quantity and quality of goods and services which a family is accustomed to consume decide their standard of living and this is determined by the income of the family.

The farmers obtain money income from different sources - from crop and livestock production, through non-agricultural occupations like trade, service, etc., as also through remittances from relatives.

Net income, expenditure and savings

The net income at total cost obtained from different sources, household expenditure and savings are shown in Table 7.1 and 7.2. The net income per family on an average was worked out to Rs.27,357.70. It was the highest in S₅, Rs.51,191.45, 3 times higher than that in S₁. The average household expenditure amounted to Rs.8160.64. It was found to be increasing with an increase in the holding size.

The surplus left on the gross income after meeting the expenditure on different items is considered as net savings. On an average Rs.19,197.06 was left as savings per family per year. The average per capita savings worked out to Rs.2926.38 per annum. The extent of savings, both per family and per capita is seen to increase with an increase

**Table 7.1. Net income, expenditure and net savings per family
(size groupwise)** (in rupees)

	S ₁	S ₂	S ₃	S ₄	S ₅	Average
1. Net income from agriculture and other sources	14194.00	12543.27	19550.21	41495.28	51191.45	27357.70

**Table 7.2. Net income, expenditure and net savings per family
(Income groupwise)** (in rupees)

	I ₁	I ₂	I ₃	I ₄	I ₅	Average
1. Net income from agriculture and other sources	4642.06	13300.53	19071.74	25583.94	75180.23	27357.70
2. Family expenditure per year	6423.15	7555.57	8580.68	9579.74	9548.78	8160.64
3. Savings/dissavings						
a) Per family	-1781.09	5744.96	10491.06	16004.20	65631.45	19197.06
b) Per capita	-296.85	886.57	1536.03	2216.65	9825.07	2926.38

in the size of holdings. While the savings per family was only Rs.5513.28 for S_2 , the lowest, it was more than seven times higher for S_5 amounting to Rs.40,881.75.

A comparison of per capita savings showed that it was Rs.918.88 for S_2 , the lowest, and Rs.6251.03 for S_5 , the highest.

The per capita savings ranged from a deficit of Rs.296.85 in I_1 to savings of Rs.9825.07 in I_5 . The extent of savings indicated that there was no margin left for investment and to meet any sudden unpredictable expenditure in the smallest income group.

Debt pattern

A split up of the sourcewise loans availed (as shown in Table 7.3 and 7.4) showed that the extent of loans advanced by the co-operatives and the Nationalised Banks on an average remained more or less the same. Other sources supplied about 12 per cent of the total loans. The average amount of loan taken per family worked out to Rs.850.50. The lower income groups were found to avail greater extent of loans.

Investment on household articles

Other than food, shelter and clothing, there are other items which adds comfort to life. Information on the materials possessed by the farm families give additional understanding about the standard of living. The total investment

Average		371.75 (43.71)	374.00 (43.97)	104.75 (12.32)	850.50 (100.00)

(Figures in parentheses are percentages to total for the respective groups)

per family and per capita were worked out and are presented in Table 7.5 and 7.6.

From the Table 7.5 it can be seen that the average expenditure per family on household articles was worked out to Rs.4036.50 and per capita expenditure Rs.615.32. Of the total investment, furniture accounted for 20.63 per cent, followed by motor vehicles (18.83 per cent), Almirah (10.75 per cent), fan (11.40 per cent), utensils (8.57 per cent), bicycles (5.00 per cent) and the rest 14.67 per cent accounted for items like sewing machine, pressure cooker, electric iron, boxes and wall clock. Among the size groups, the total expenditure per family was found to be increasing with an increase in the size of holdings.

With regard to different items the average number of radio per family was found to be increasing with an increase in the holding size. Same trend was noted in items like bicycle, fan, pressure cooker, electric iron and Almirah. The expenditure noticed to be increasing with an increase in income.

The number of almost all the items purchased per family was found to increase with an increase in income. The difference can be attributed to the purchasing power and preference of the highest income groups to buy these items - and it is a clear indication of the higher standard of living of the higher income groups.

Constituents of family expenditure and standard of living

The average expenditure per family per year for the different items are presented in Table 7.7, size groupwise and in 7.8 income groupwise. The expenditure per adult unit is also worked out and are shown.

The average expenditure per family was found to be Rs.8160.64 per year and Rs.1433.25 per adult unit per year. it was observed that the food items accounted for the major portion of expenditure of farm families, accounting for 67 per cent of the total. The expenditure per family on food items alone on an average was Rs.5467.27 which worked out to Rs.960.21 per adult unit.

Among the food items, protective foods constituted an expenditure of 54.17 per cent, and cereals 44.21 per cent. The expenditure on pulses was only 1.62 per cent.

The next important item was clothing which constituted 13.95 per cent of the total expenditure. The expenses on education, travel, fuel and lighting, recreation, etc. together was around 20 per cent.

It was found that the percentage expenditure on food decreased with the increase in the size of the holding ranging between 75 per cent in S₁ to 60 per cent in S₅. The percentage expenditure on clothing, education and house tax etc. found to increase with an increase in size of the holdings.

Table 7.8. continued

Adult units		120.05	129.43	136.16	55.90	127.84	569.38

With regard to education and recreation, the proportional expenditure in S_5 was found to be much higher than in S_1 , 7.95 and 1.06 per cent for education and 5.23 and 1.64 for recreation respectively for S_5 and S_1 .

Among the size groups the expenditure per farm was found to increase with an increase in the size of the holding. It was Rs.10,309.70 in S_5 , 52.56 per cent higher than that recorded in S_1 (Rs.6757.61).

In general the expenditure on the various items among income groups was found to be increasing with the increase in income. The details are presented in Table 7.8.

Eventhough the absolute expenditure per family on protective foods was found to be increasing with increase in income, the percentage expenditure on those item was found to be almost the same among the various income groups. While taking into consideration the expenditure on total food - comprising cereals, pulses and protective foods - the percentage contribution to total expenditure was found to be decreasing with an increase in income. Percentage expenditure on clothing, education and recreation was found to increase with an increase in income while that on fuel decrease.

Consumption of protective foods

Protective food is an important item of diet. Foods rich in proteins, vitamins and minerals are termed as protective food. This group of foods include milk, meat, fish, egg, vegetables, fruits, etc.

The expenditure on important items of protective foods per family and per adult unit in different size groups of holdings is presented in Table 7.9.

It can be observed that the expenditure on protective foods per family was Rs.2961.77 per year on an average, which worked out to Rs.520.17 per adult unit per year. Among the items of protective foods, the expenditure on milk and milk products were the maximum accounting for 23.43 per cent followed by fish (12.78 per cent), meat (12.31 per cent), vegetables (11.52 per cent), edible oils (10.88 per cent). Among the size groups, the expenditure on protective food was found to be the maximum in S₅ - both per family and per adult unit - which worked out to Rs.3681.28 per family and Rs.649.55 per adult unit. The expenditure on protective food was found to be higher in the larger size groups than the smaller groups indicating that the farmers having larger holdings have a better standard of living than those with smaller holdings.

Among the income groups, the expenditure per family as well as per adult unit on protective foods was found to be increasing with an increase in income (Table 7.10). The expenditure per adult unit was higher for I₅ (Rs.587.26). The percentage expenditure on milk and milk products, meat, fish and egg was relatively higher in the higher income groups, indicating a better standard of living.

Summary

SUMMARY

The present study was conducted with a view to understand the socio-economic status of farmers in Irinjalakkuda Block in the Peechi Command Area. The specific objectives of the investigation were the following.

1. To study the methods and practices followed for cultivation;
2. To study infrastructural facilities available;
3. To understand general, social and economic conditions of farmers in the locality;
4. To study cost and income structure of the farm business;
5. To assess the availability and use of resources;
6. To study savings, investments, assets and debts pattern; and
7. To understand the consumption pattern and standard of living of the farmers.

One hundred farm families were selected at random from five Panchayat wards in the Block. The data were collected by survey method during the months of March, April and May 1982 and the reference period was the agricultural year 1981-82.

1. Methods and practices followed for cultivation

Farm holdings in the area were very small. Yet, each farmer was found to possess more than one fragment consisting of wet lands and garden lands. Wet lands were under paddy. Garden lands were put under a variety of crops such as coconut, arecanut, banana, cashew, pepper, etc. The cultivation practices of paddy, coconut, arecanut and banana only were studied.

Paddy

Paddy is grown in two seasons, namely Mundakan and Puncha. For both these seasons, the cultivation practices remains more or less the same with slight variations to adjust to the prevailing climatic conditions. Paddy cultivation is concentrated in 'kole lands' which remain submerged under water for almost six months in an year. Ploughing is done either by tractor or by bullocks. Seed treatment is not practised. Cowdung is the organic manure commonly applied. Fertilizers are applied by majority of the farmers. Hand-weeding is the common practice. Plant protection chemicals of different varieties are in use. Women are generally employed for harvesting.

Coconut

Before monsoon starts in May, the basins of coconut trees are cleared and fertilizers or manures are applied. By January basins are opened up to enable irrigation. Palms are irrigated

2 to 3 times a week. Harvesting is done 6 to 7 times in an year.

Areca nut

The maintenance operations in respect of areca nut were more or less similar to that for coconut. Irrigation and manures were not applied regularly. No farmer was found to apply fertilisers for this crop. Sale of produce was mainly on contract.

Banana

Systematic planting of banana was not found common and it was planted mixed with other crops. As a rainfed crop planting new suckers is undertaken during April-May and wherever irrigation facilities are available the crop is planted during August-September. No definite spacing was seen adopted. Fertilisers are rarely applied. Irrigation is given twice a week. Plant protection measures are not adopted. Prepping is done to avoid damages.

2. Infrastructural facilities in the block area

The infrastructural facilities available were found to be satisfactory. The services of primary co-operatives as well as commercial banks were available in the block area. The block is well connected by roads. National Highway-47 passes through the eastern part of this block. Peechi and Chalakkudy irrigation projects supply irrigation water to the various

parts of the block. Even though in some parts of the block, the farm to market transportation facilities were found to be insufficient, generally the communication and marketing facilities can be said to be satisfactory.

3. General characteristics of the sample farms

The total members in the respondents families were 656, of which 51.98 per cent were males and 48.02 per cent females, the average family size was 6.56. 68.44 per cent of the people came in the age group of between 15 and 60. The literacy percentage of the males was found to be 87.68 and that of females 82.54, the average being 85.21. About 64 per cent of the sample families were found to get income from other occupations also. The net cropped area on an average worked out to 1.21 hectares. The total cropped area on an average for the selected farms worked out to 1.35 hectares. Paddy, coconut and arecanut occupied 58.51, 32.97 and 3.64 per cent of the total cropped area respectively. The cropping intensity was found to be 111.

4. Cost and income structure of farm business

Costs and returns of paddy (Mundakan and Pancha), coconut, arecanut and banana were worked out. The cost of cultivation per hectare on the average for high yielding varieties and local varieties during Mundakan worked out to Rs.4186.60 and Rs.3426.70 with an yield of 33.58 quintals and 23.79 quintals of paddy respectively. The total cost

excluding rental value of land were worked out to Rs.2860.60 and Rs.2411.21 respectively. The value of straw obtained were Rs.1285.82 and Rs.1101.82. The value of total output worked out to Rs.6629.98 and Rs.5064.62. Cost per quintal for Mundakan HYVs was Rs.73.13 and LVs Rs.86.21. Excluding rental value of land cost per quintal worked out to Rs.35.51 and Rs.47.33 for HYVs and LVs, respectively during Mundakan season. The benefit-cost ratios worked out at total cost to 1.58 and 1.48 respectively.

The cost of cultivation per hectare on the average for HYVs and LVs during Puncha worked out to Rs.4959.11 and Rs.4498.27 with an yield of 33.82 quintals and 25.89 quintals of paddy respectively. The total cost excluding rental value of land worked out to Rs.3688.42 for HYVs and Rs.3402.43 for LVs. The value of straw obtained were Rs.1177.92 and Rs.1334.22 for HYVs and LVs respectively. The total value of output worked out to Rs.6453.48 and Rs.5479.18. Cost per quintal at total cost and at cost excluding rental value of land were Rs.104.29 and Rs.67.78 for Puncha HYVs and Rs.115.30 and Rs.77.44 for Puncha LVs respectively. The benefit-cost ratios at cost C were 1.30 and 1.22 respectively.

The average cost of maintenance of coconut per hectare worked out to Rs.6330.79 and average yield was found to be 9995.83 nuts per hectare. The total maintenance cost excluding rental value of land worked out to Rs.3552.44. The

value of total output was Rs.13,891.77 with a net return of Rs.7560.98 over variable cost.

The total cost of maintenance per hectare for arecanut worked out to Rs.4565.16, while the gross income Rs.5728.74, resulting in a net return over variable cost of Rs.1163.58.

The cost of cultivation of banana per hectare, on an average, worked out to Rs.36248.82 and excluding rental value of land it was Rs.27235.17. The gross income was Rs.45068.23 giving a net return of Rs.8819.41 over total cost.

The costs and returns for milch animals were also worked out. The maintenance cost of crossbred cows and desi cows worked out to Rs.2490.64 and Rs.1389.73 per animal per year. Total receipts amounted to Rs.2685.40 and Rs.1846.25 per animal per year for cross-bred cows and desi cows respectively giving a marginal return over variable cost of Rs.194.76 and Rs.456.52 per year. Maintenance of buffaloes was found to give a profit of Rs.974.65 per animal per year. Draft animals were not maintained throughout the year. The net income per farm from livestock and poultry was Rs.2510.36 on an average.

From an analysis of farmstead as a whole it was found that the average expenditure per farm on crop and livestock amounted to Rs.6111.45 of which 24.13 per cent was on livestock. The gross income worked out to Rs.14303.56 of which 17.55 per cent from livestock. The net income per farm worked out to Rs.8192.11. The study showed that in order to meet the

household expenditure at the current level from net income from crops and livestock alone, the average farmer in the study area should possess a net area of 1.21 hectares. But if he has to depend solely upon crop production alone, then he must have an area of 1.38 hectares in his possession. The smaller farms were not in a position to meet the household expenditure from the tiny area they possess.

5. Use of resources

The cultivation operations were carried out mostly by human and bullock labour. For paddy cultivation on an average 72.21 hours of male labour and 988.17 hours of female labour were found to be employed. For the crops coconut, arecanut and banana, the respective figures were 169.08 and 20.28; 108.16 hours of male labour with no female labour and 2915.83 and 19.10 respectively. Tractor was also employed to a limited extent substituting bullock labour mainly for the preparation of land for paddy cultivation. On an average 29.02 hours of bullock labour and 3.79 hours of tractor were found to be employed for one hectare of paddy cultivation. Dependence of family labour was found to be more in the smaller size groups than in the larger size groups. The utilization of fertilizers was far below the recommendations. On an average 26.38 kg N, 16.12 kg P and 26.33 kg K were found to be applied per hectare of paddy. As area of holding increased

fertilizer use per hectare was found to decrease while as income of households increased, fertilizer use was found to increase.

6. Savings, investments, assets and debts pattern

On an average the savings per family worked out to Rs.19,197.06 and the per capita savings was Rs.2926.36. The average value of household articles per family worked out to Rs.4036.50 and per capita investment on these items was Rs.615.32. The total investment per farm in different capital assets such as land, livestock, implements, buildings and others worked out to Rs.4,12,672.25. Land accounted for 94.13 per cent of the total assets. The average amount of loans taken per family worked out to Rs.850.50. The extent of loans taken from the co-operatives and the nationalised commercial banks on an average remained more or less the same, around 43 per cent.

7. Consumption pattern and standard of living

Of the average household expenditure per farm of Rs.8160.64 per year, expenditure on food accounted for 57 per cent. ^{of} The total expenses on food, ^{cereals} accounted for 44.21 per cent and pulses constituted 1.62 per cent. Proportion of expenditure on food to total expenditure decreased with an increase in the size of the holding as well as income. The expenditure on costly food items like fish, meat and milk

showed a positive relationship with the size of holding and gross income of the families depicting the higher standard of living of the larger holding size groups and higher income groups.

4. Coir ropes

VIII. IRRIGATION STRUCTURE & EQUIPMENT

Sl. Item No.	No. Fragment No.	Specification	Year of construction	Value at construction/ purchase cost (Rs)	Annual maintenance cost (Rs)	Remarks
--------------	------------------	---------------	----------------------	---	------------------------------	---------

1. Well

2. Tubewell

3. Pump set

4. Pump shed

5. Pond

6. Channels

IX. OPERATIONAL COSTS

Sl. Item No.	No. of hrs./ day	No. of days/ week	No. of month in a year	Fuel cost	Maintenance cost/ year		Remarks
					Major re-pairs last year	Annual maintenance cost	

1. Tractor

2. Power tiller

3. Pumpset

X. INCOME FROM RENTING OUT

Sl. No.	Item	Hours rented out	Rate/hour (Rs)	Total rent (Rs)	Remarks
---------	------	------------------	----------------	-----------------	---------

1 Tractor

2 Power tiller

3 Pumpset

4 Sprayer

5 Drought animals

6 Bullock cart

7 Hand cart

XI. LIVESTOCK

Description	Breed	Age	Home bred/ pur- chase	Year of pur- chase/ birth	Purchase price/ market value	Present worth	Remarks
-------------	-------	-----	-----------------------------	------------------------------------	---------------------------------------	------------------	---------

I. Milch animals

1. Buffaloes

2. Cows

II. Young stock

1. Heifers

a. Male

b. Female

2. Buffaloes

a. Male

b. Female

III. Drought animals

IV. Goats

V. Poultry

XII. MAINTENANCE CHARGES OF LIVESTOCK/DAY/ANIMAL

Type of animals	No. of animals	Green fodder		Dry fodder				Concentrates			Mineral mixture		Veterinary expenses	Remarks	
		Qty.	Value	Qty.	Value	Qty.	Value	Qty.	Value	Qty.	Value				
		Home prod-used	Pur-cha-sed	HP	Pur.	HP	Pur.	HP	Pur.	HP	Par				

XIII. STATUS OF MILCH ANIMALS

Milch animals	Present status	No. of completed lactations	Date of previous calving	Date of present calving	Total lactation period	Milk yield (in litres)			Milk consumed (in litres)	Milk sold Qty. (litrs)	Value (Rs.)	Converted to other products		Present worth of animal	Remarks
						1st	2nd	3rd				Used	Value		
						1/3	1/3	1/3							

XIV. INCOME FROM BIRDS

Sl. No.	Type	No. of birds laying eggs	Total No. of eggs	No. of eggs consumed	No. of eggs sold	Value
---------	------	--------------------------	-------------------	----------------------	------------------	-------

XV. INCOME FROM DUNG

Approximate quantity available	Used within the farm	Quantity sold	Total amount
--------------------------------	----------------------	---------------	--------------

XVI. HOUSEHOLD ARTICLES

Sl. No.	Item	Year of purchase	Purchase price	Maintenance cost	Present worth	Remarks
1	Radio					
2	Sewing machine					
3	Bicycle					
4	Motor cycle					
5	Scooter					
6	Motor car					
7	Fan					
8	Pressure cooker					
9	Electric iron					
10	Almirah					
11	Boxes					
12	Furniture					
13	Utensils					
14						
15						

XVII. SOURCES OF POWER

Sl. No.	Purpose	Device	Material	Expense/month	Remarks
1	Cooking				
2	Lighting				
3	Irrigation				
4	Transport of farm product				

XVIII. MARKETING OF FARM PRODUCE

Sl. No.	Item	Quantity sold	To whom sold	Where sold	Distance to the nearest market	Mode of transport	Marketing problems if any
----------------	-------------	----------------------	---------------------	-------------------	---------------------------------------	--------------------------	----------------------------------

XIX. CONSUMPTION PATTERN OF THE FAMILY

Sl. No.	Particulars	Quantity in kg. per Day/Week/Month/Year	Rate per unit	Total amount per year	Remarks
---------	-------------	--	---------------------	-----------------------------	---------

A. Food

1. Rice
2. Tapioca
3. Wheat
4. Pulses
5. Sugars
6. Oils
7. Milk
8. Meat
9. Fish
10. Egg
11. Vegetables

B. Clothing & Footwear

C. Rent

D. Fuel & lighting

E. Education

F. Medicine

G. Travel

H. Recreation

I. Beverages

J. Taxes

K. Tobacco

L. Liquor

M. Others, if any

XX. LOANS AND SAVINGS:

1. Loans obtained

Sl. No.	Agency	Date of borrowing	Purpose	Amount	Interest rate	Amount outstanding	Amount due
----------------	---------------	--------------------------	----------------	---------------	----------------------	---------------------------	-------------------

ii. Savings like loans advanced, jewellery, shares, cash in bank, cash in hand, deposits, etc.

Sl.No.	Form of saving	Year	Present value	Remarks
---------------	-----------------------	-------------	----------------------	----------------

XXI. SAVINGS & INVESTMENTS:

A. Acquisition of real estate, buildings, vehicles

Sl. No.	Month	Acquisition/ improvement	Acquisition/ improvement cost	Remarks
----------------	--------------	-------------------------------------	--	----------------

B. DISPOSAL

Sl.No.	Item	Year	Disposal value	Remarks
---------------	-------------	-------------	-----------------------	----------------

XXIV

Sl. No.	Name of crop	Name of chemical	PLANT PROTECTION				IRRIGATION					
			Qty.	Va- lue	Labour for application							
					Men		Semen		Men		Women	
					Family	Hired	Family	Hired	Family	Hired	Family	Hired
No.	Days	Ant.	No.	Days	Ant.	No.	Days	Ant.	No.	Days	Ant.	

1. Seasonal
2. Annual
3. Perennial

XXV. FERTILIZERS AND MANURES AND THEIR APPLICATION

Sl. No.	Name of crop	Fertilisers		Manures		Application							
		Name	Qty.	Value	Name	Qty.	Value	Men		Women		Hired	
								Family	Hired	Family	Hired	Hired	
								No.	Days	Ant.	No.	Days	Ant.

1. Seasonal
2. Annual
3. Perennial

XXVI.

Sl. No.	Name of crop	HARVESTING								KIND PAYMENTS		YIELD			
		Men				Women				Quantity (kg)	Value (Rs)	Main product		By products	
		Family		Hired		Family		Hired				Quantity (in kg)	Value (in Rs)	Quantity (in kg)	Value (in Rs)
		No.	Days	Ant.	No.	Days	Ant.	No.	Days	Ant.	No.				
1	Seasonal														
2	Annual														
3	Perennial														

XXVII. CONSTRAINTS IN PRODUCTION:

Sl. No.	Description	Rating in a scale according to magnitude of the problems
1	Availability of fertilizers	
2	High price of fertilizers	
3	Lack of capital	
4	Non-availability of credit	
5	Lack of irrigation facilities	
6	Non-availability of high yielding seeds	
7	Lack of marketing facilities	
8	Lack of communication facilities	
9	Low price of farm produce	
10	Small size of farms	
11	Non-availability of labour	

Appendix II

Table II.1. Inputwise cost of cultivation per hectare of HYV paddy - Pancha (size groupwise)

(in rupees)

**SOCIO-ECONOMIC STUDY OF FARMERS IN
IRINJALAKUDA BLOCK IN THE
COMMAND AREA OF PEECHI
IRRIGATION PROJECT**

By

LATHA BASTINE C.

ABSTRACT OF THE THESIS

Submitted in partial fulfilment of the
requirement for the degree of

Master of Science in Agriculture

Faculty of Agriculture
Kerala Agricultural University

Department of Agricultural Economics
COLLEGE OF HORTICULTURE
Vellanikkara - Trichur

1982

ABSTRACT

The study was undertaken with the following objectives, viz., to study the methods and practices followed for cultivation, the general, social and economic characteristics of the farmers in the study area, cost and income structure of the farm business, the resource use; and the savings, investment, assets and debts pattern.

One hundred farm families were selected by two stage random sampling, from whom the relevant data were collected using a well structured schedule.

The methods and practices followed for cultivation of different crops were found to be more or less the same in different parts of the block. Generally, two crops of paddy (Mundakan and Puncheda), coconut, arecanut and banana were the major crops grown.

Dependence on hired labour was high in the area. Tractor power was substituted for bullock power to a limited extent. Dependence of family labour was more in smaller size groups. The utilization of fertilizers was below the recommended levels. The per hectare use was found to decrease with increase in the size of the holdings and increase with increase in income.

The cost of cultivation for Mundakan season was found to be lower than that of Puncheda, mainly due to differences

in cultivation operations. Even though yield was slightly higher, the cost per quintal was also higher during Pancha than Mundakan. Thus the study showed that Mundakan paddy was more profitable than Pancha due to lower cost of cultivation.

Even though cost of cultivation was found to decrease with increase in size of holding no clearcut association was found between family income and cost of cultivation.

Though the cultivation of coconut and banana resulted in high net returns they involved heavy investment also. Arecanut cultivation in the area was found to be in a declining stage.

Expenditure on food did not show much difference among different holding size groups and income groups except in the highest income group and largest holding size group. Expenditure on costly food items like, fish, meat and milk showed a positive relationship with the size of holding and gross income of the families. Only the farmers in the higher income groups were able to meet the household expenditure from the net income obtained from crop production and livestock.

The infrastructural facilities in the area were found to be satisfactory. There were sufficient credit, communication and marketing facilities in the area. But in some parts of the block, transport facilities are yet to be developed.
